DESCRIPTION

There are two different style's of overhead console (1) available on this vehicle, High line and Mid or Low line. All overhead consoles are equipped with a sunglasses storage bin (2) and two reading and courtesy lamps (4). On High line models, the reading lamps are a Light Emitting Diode (LED) multi directional design, and on the Mid or Low line design the lamps are fixed with a replaceable incandescent bulb. The sunglasses storage bin also has a conversation mirror that is visible when the bin is locked in the partial open position. On vehicles equipped with a power sunroof, the sunroof switch (5) is located behind the sunglasses bin. On vehicles equipped with automatic climate control an infrared temperature sensor (3) is located between the reading and courtesy lamps. Both overhead console designs are mounted with six snap clips into a molded plastic retainer bracket located above the headliner to provide secure overhead console attachment.

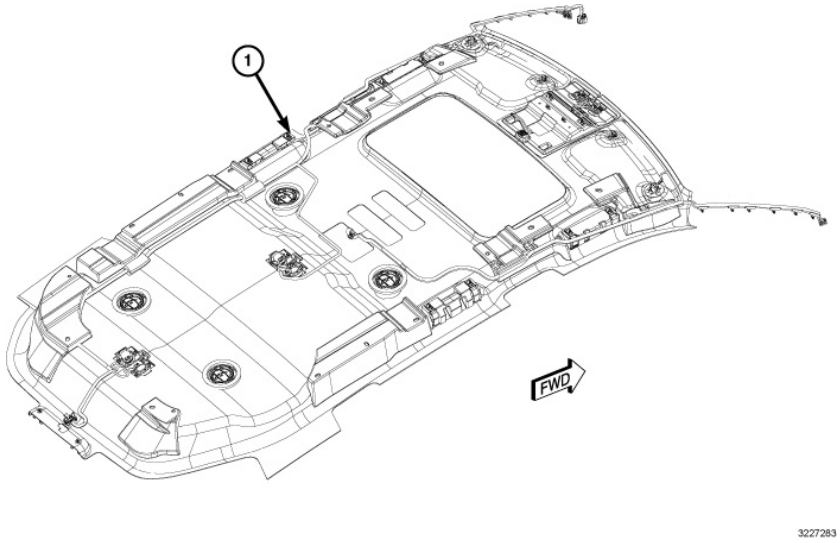
INSTALLATION

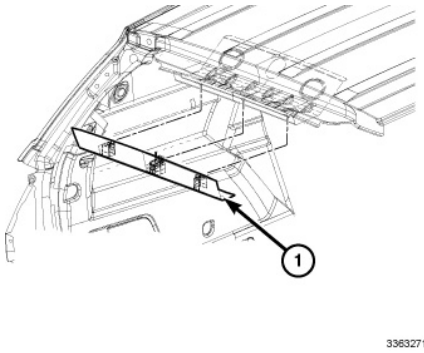
Labor Operations: Click to display a list of Labor Operations associated with this procedure

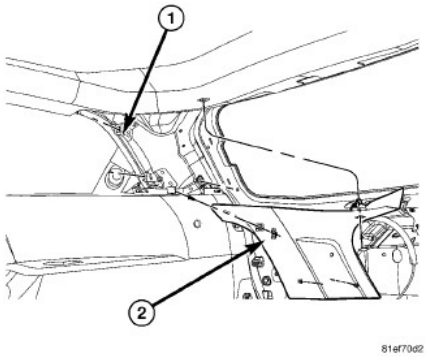


NOTE: In the event the headliner is damaged or creased during removal, it will need to be replaced with a new headliner.

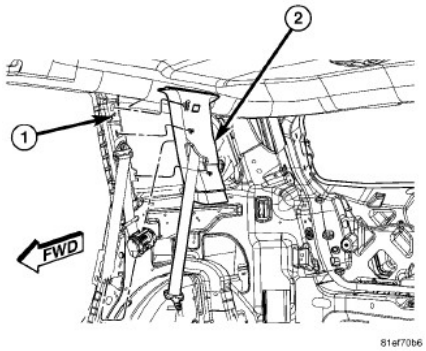
1. With the help of an assistant(s), carefully install the headliner (1) into the vehicle through the rear liftgate opening. Do not over flex the headliner and be carefully not to crack or mar the headliner.
2. Raise the headliner (1) into position and engage the retainers.
3. Install the pushpin retainers at the rear of the headliner.
4. Connect the electrical connectors.
5. Install the grab handles and coat hooks. Install the mounting fasteners.
6. Install the quarter trim panel to the vehicle, (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Installation) .
7. Install the overhead console, (Refer to 23 - Body/Interior/CONSOLE, Overhead - Installation) .
8. Install the D-pillar trim panel (2), (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Installation) .
9. Install the seat belt mounting bracket to the right D-pillar.

10. Install the rear header trim panel (1) by aligning the retaining tabs and hand tapping the trim to engage the retainers.

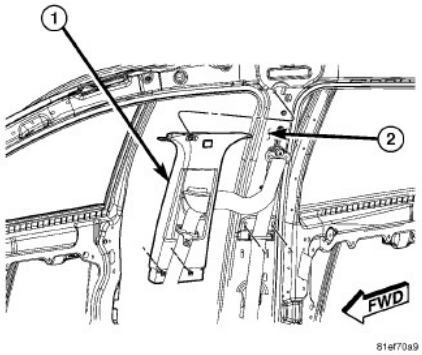




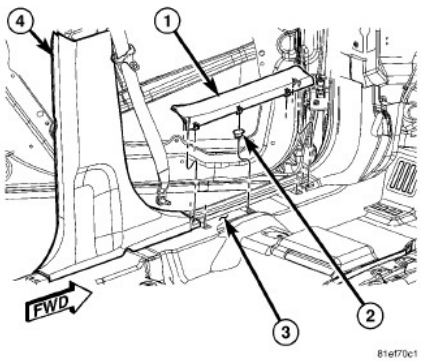
11. Install the C-pillar trim panel (2), (Refer to 23 - Body/Interior/PANEL, C-Pillar Trim - Installation) .



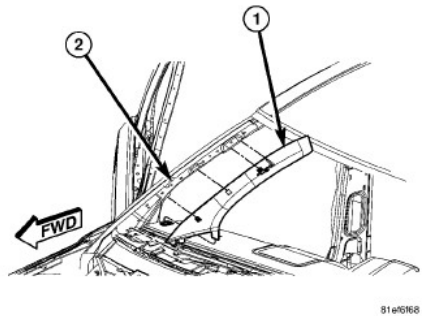
12. Install the upper B-pillar trim panel (1), (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Installation) .



13. Install the lower B-pillar trim panel (4), (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Installation) .



14. Install the A-pillar trim panel, (Refer to 23 - Body/Interior/PANEL, A-Pillar Trim - Installation) .



CAUTION: **When removing or installing the screws (1), be certain to avoid any wiring or drain tube interference.**

15. Install the sun visor support and mounting fasteners.

16. If equipped, connect the wire harness connector for the illuminated vanity mirror (4).

17. Install the sun visors and mounting fasteners.

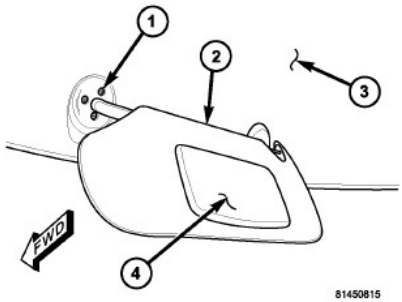
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: In the event the headliner is damaged or creased during removal, it will need to be replaced with a new headliner.



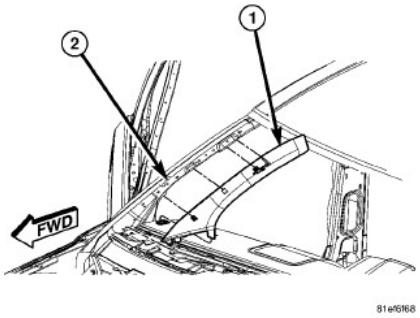
1. Remove the three screws (1) that secure each sun visor (2) to the roof panel and remove the visor from the headliner (3).

CAUTION: **When removing or installing the screws (1), be certain to avoid any wiring or drain tube interference.**

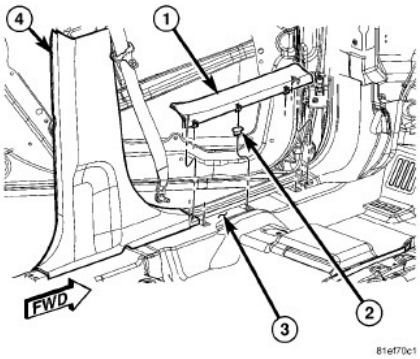
2. If equipped, disconnect the wire harness connector for the illuminated vanity mirror (4).

3. Remove the sun visor support mounting fasteners and remove the support from the headliner (3).

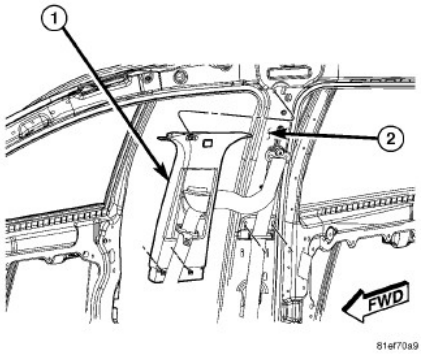
4. Remove the A-pillar trim panel (1), (Refer to 23 - Body/Interior/PANEL, A-Pillar Trim - Removal) .



5. Remove the lower B-pillar trim panel (4), (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Removal) .

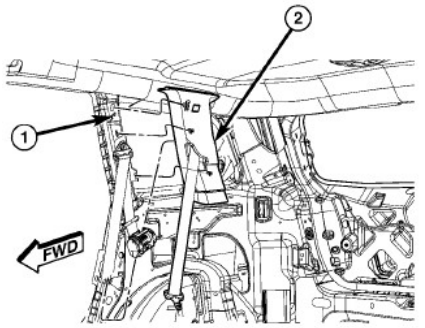


6. Remove the upper B-pillar trim panel (1), (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Removal) .



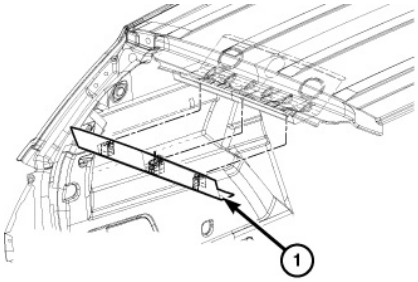
81ef70a9

7. Remove the C-pillar trim panel (2), (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Removal) .



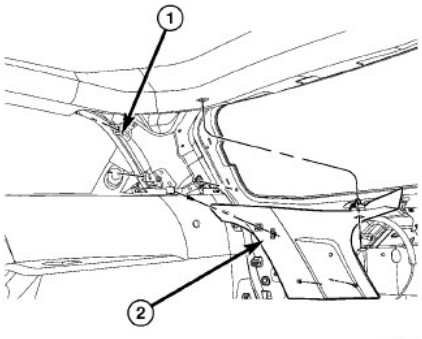
81ef70b6

8. Remove the rear header trim panel (1) by carefully pulling down on the trim to disengage the retainers.



3363271

9. Remove the D-pillar trim panel (2), (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Removal) .
10. Remove the overhead console, (Refer to 23 - Body/Interior/CONSOLE, Overhead - Removal) .
11. Remove the seat belt mounting bracket from the right D-pillar.



81ef70d2

12. Remove the grab handles and coat hooks.

13. Remove the left quarter trim panel. (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Removal) .

14. Lower the first and second row seats as far as possible, remove the headrests if necessary.

15. Disconnect electrical connectors.

16. Remove the pushpin retainers at the rear of the headliner.

17. Carefully disengage retaining clips and lower headliner (1).

18. With the help of an assistant(s), remove the headliner (1) from the vehicle through the lift gate opening.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

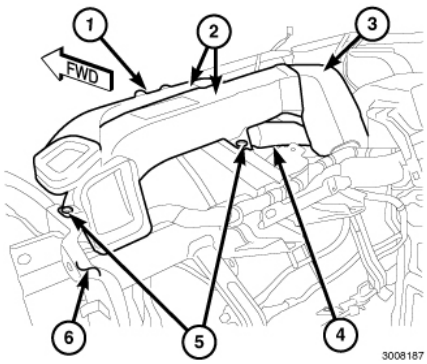
WARNING: **Disable the airbag system before attempting any steering wheel, steering column or instrument panel component diagnosis or service. Disconnect and isolate the negative battery (ground) cable, then wait two minutes for the airbag system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the airbag system. Failure to follow these instructions may result in accidental airbag deployment and possible serious or fatal injury.**

NOTE: The demister ducts are serviced with the instrument panel ducts as an assembly.

NOTE: LHD model shown in illustrations. RHD model similar.

1. Disconnect and isolate the negative battery cable.
2. Remove the instrument panel cover (Refer to 23 - Body/Instrument Panel).
3. Remove the three push-pin retainers (1 and 5) that secure the driver side instrument panel and demister duct assembly (2) to the top of the instrument panel support (6).
4. Disconnect the driver side instrument panel and demister duct assembly from the instrument panel center duct (3) and the defroster duct (4) and remove the driver side instrument panel and demister duct assembly.



5. Remove the two push-pin retainers (4) that secure the passenger side instrument panel and demister duct assembly (1) to the top of the instrument panel support (5).
6. Disconnect the passenger side instrument panel and demister duct assembly from the instrument panel center duct (2) and the defroster duct (3) and remove the passenger side instrument panel and demister duct assembly.

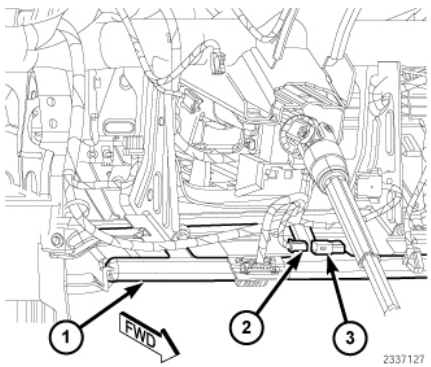
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: The Light Emitting Diode (LED) and printed circuit board for these lamps are serviced only as a unit with the courtesy lamp assembly. If any part of these lamps is damaged or ineffective, the entire lamp assembly must be replaced.



1. Position the courtesy lamp (3) under the lower edge of the instrument panel steering column opening (driver side) or glove box opening (passenger side) lower reinforcement (1).
2. Reconnect the instrument panel wire harness connector (2) to the connector receptacle integral to the courtesy lamp.
3. Align the push-in plastic retainer on the underside of the courtesy lamp with the mounting hole in the instrument panel lower reinforcement.
4. Using hand pressure, press the courtesy lamp downward firmly and evenly until the push-in plastic retainer is fully engaged in the mounting hole.
5. If the vehicle is so equipped, reinstall the closeout panel under the driver or passenger side of the instrument panel. (Refer to 23 - Body/Instrument Panel/PANEL, Silencer - Installation) .
6. Reconnect the battery negative cable.

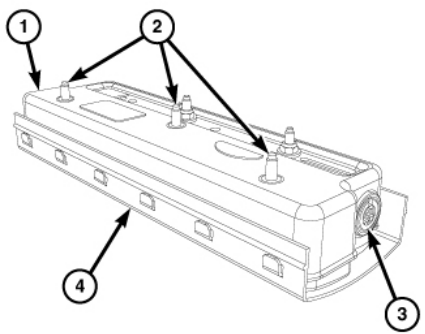
DESCRIPTION

A Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB) is used on vehicles manufactured for domestic markets. These airbags are passive, inflatable, Supplemental Restraint System (SRS) components. Vehicles with this equipment may be readily identified by the **SRS - AIRBAG** logo located on the upper outboard corner of the instrument panel steering column opening cover.

The KAB is concealed behind the steering column opening cover below the steering column on the driver side lower instrument panel. Located behind the steering column opening cover, the stamped metal airbag housing (1) is secured by three studs (2) with nuts to the stamped metal instrument panel lower reinforcement and mounting plate. A molded plastic protective cover (4) is secured over the folded airbag cushion by numerous hook formations stamped into the airbag housing that are engaged through window openings in the outer perimeter of the cover.

The airbag housing contains the airbag inflator and a heat shield. The airbag inflator is a single-initiator, non-azide hybrid-type unit that is secured to the housing by two studs with nuts and sealed within the airbag housing. The airbag is connected to the vehicle electrical system through a dedicated take out and connector insulator of the instrument panel wire harness that connects directly to the inflator initiator (3).



The KAB cannot be repaired, and must be replaced if deployed, ineffective or in any way damaged. If the airbag is deployed, the KAB and the steering column opening cover must be replaced.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the Inflatable Knee Blocker (IKB) airbag, or becoming entrapped between the IKB airbag cushion and the IKB cover. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the KAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .

1. Position the Knee AirBag (KAB) to the mounting plate on the instrument panel lower reinforcement.
2. Install and tighten the three nuts that secure the KAB studs to the mounting plate below the instrument panel. Tighten the nuts to 6 N·m (53 in. lbs.).
3. Reconnect the connector insulator of the instrument panel wire harness take out for the KAB to the inflator initiator connector receptacle by pressing straight in on the connector. You can be certain that the connector is fully engaged in its receptacle by listening carefully for a distinct, audible click as the connector latches snap into place.
4. Reinstall the steering column opening cover onto the instrument panel. (Refer to 23 - Body/Instrument Panel/COVER, Steering Column Opening - Installation) .
5. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB) is deployed by an electrical signal generated by the Occupant Restraint Controller (ORC) to which it is connected through a KAB line 1 (or squib) circuits to the initiator in the airbag inflator. The hybrid-type inflator assembly for the airbag contains a small canister of highly compressed inert gas. When the ORC sends the proper electrical signal to the airbag inflator, the electrical energy creates enough heat to ignite chemical pellets within the inflator.

Once ignited, these chemical pellets burn rapidly and produce the pressure necessary to rupture a containment disk in the inert gas canister. The inflator is sealed to the airbag cushion and a diffuser in the inflator directs all of the inert gas into the airbag cushion, causing the cushion to inflate. As the cushion inflates, the KAB protective cover will split at predetermined tear seam lines concealed on the underside of the cover, then fold open and out of the way.

The cushion protects the lower extremities of the vehicle operator and helps to keep the seat occupant properly positioned for the Driver AirBag (DAB) deployment during a frontal impact collision. Following an airbag deployment, the KAB cushion quickly deflates by venting the inert gas through the loose weave of the fabric used to construct the instrument panel side of the airbag cushion, and the deflated cushion hangs down loosely from the lower instrument panel.

The ORC monitors the condition of the KAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the KAB initiator and squib circuit requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag cushion and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

NOTE: The following procedure is for replacement of an ineffective or damaged Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the KAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .

1. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Remove the steering column opening cover from the instrument panel. (Refer to 23 - Body/Instrument Panel/COVER, Steering Column Opening - Removal) .
3. Disconnect the electrical connection that is secured by integral latches to the airbag inflator initiator connector receptacle on the inboard end of the Knee AirBag (KAB) housing. Depress the latches on each side of the connector insulator and pull the insulator straight out from the inflator initiator to disconnect it from the connector receptacle.
4. Remove the three nuts that secure the KAB to the mounting plate on the lower instrument panel reinforcement.
5. Remove the KAB from the vehicle.

SUPPLEMENTAL RESTRAINT STORAGE

Airbags and seat belt tensioners must be stored in their original, special container until they are used for service. Also, they must be stored in a clean, dry environment away from sources of extreme heat, sparks and high electrical energy. Always place or store any airbag on a surface with its trim cover or airbag cushion side facing up, to minimize movement in case of an accidental deployment.

BODY LUBRICATION

Lubrication Requirements

Locks and all body pivot points, including such items as seat tracks, door hinge pivot points and rollers , liftgate, tailgate, sliding doors and hood hinges, should be lubricated periodically with a lithium based grease such as Mopar ® Spray White Lube to ensure quiet, easy operation and to protect against rust and wear. Prior to the application of any lubricant, wipe the parts clean, to remove dust and grit. After lubricating, excess oil and grease should be removed. Particular attention should also be given to hood latching components to make sure they function properly. When performing other underhood services, clean and lubricate the hood latch release mechanism and safety catch.

The external lock cylinders should be lubricated twice a year, preferably in the fall and spring. Apply a small amount of a high quality lubricant such as Mopar ® Lock Cylinder Lubricant directly into the lock cylinder.

Lubricant Application

Door Lock Cylinders

1. Apply a small amount of lubricant directly into the lock cylinder.
2. Apply a small amount of lubricant to the key.
3. Insert key into lock cylinder and cycle the mechanism from the locked to the unlocked position.

   NOTE: Do not add more lubricant.

4. Cycle the lock cylinder mechanism several times to allow the lubricant to flow throughout the cylinder.
5. Wipe all lubricant from exterior of lock cylinder and key.

All Other Body Mechanisms

1. Clean component as described above.
2. Apply specified lubricant to all pivoting and sliding contact areas of component.

Lubricant Usage

Engine Oil

- door hinges - hinge pin and pivot contact areas
- hood hinges - pivot points
- liftgate hinges

Mopar ® Spray White Lube or Equivalent

- door check straps
- liftgate latches
- liftgate prop pivots
- ash receiver
- fuel filler door remote control latch mechanism
- parking brake mechanism
- sliding seat tracks
- liftgate latch

Mopar ® Multipurpose Grease or Equivalent

- all other hood mechanisms

Mopar ® Lock Cylinder Lubricant or Equivalent

- door lock cylinders
- liftgate lock cylinder

NET, FORM AND PIERCE REPAIR

CAUTION: **Failure to follow these recommendations could result in damage or failure to the part and the related parts.**

Net, form and pierce is a manufacturing process which takes place during the original build of the vehicle. The original part will have a beveled platform that will decrease toward the fastener location mounting hole. Replacement parts in these areas may not include bevel (form) and / or fastener hole (pierce) and will need to be adapted for proper fit and finish.

The primary locations which may utilize net, form and pierce are:

- Fender Reinforcement (at front end module mount)
- Fender Tower Mounts
- Hood Hinge (lower half)
- Rear Body Header (liftgate hinge mounts)
- Strut Tower (at upper control arm mount)

NOTE: Shock tower is net, pierce only.

NOTE: The thickness of shims is not to exceed the original thickness of the factory bevel. If more shims are needed damage is still present and must be repaired properly.

If the replacement part did not come with a fastener hole, one of equal size and location will have to be drilled. Body shims should be used in the fender reinforcement to front end module. The hood hinge area, fender tower mounts, and rear body header will utilize washers as spacers where a specific spacer does not exist. The shims and spacers should be sealed between each other and to the stationary surface. Care should be taken when smoothing sealer around washers to ensure undetectable repair. Refinish the repair area per the paint manufacturers recommendations for corrosion resistance and appearance purposes.

HEAT STAKING

1. Remove trim panel.
2. Bend or move the trim panel components at the heat staked joints. Observe the heat staked locations and/or component seams for looseness.
3. Heat stake the components.
    a. If the heat staked or component seam location is loose, hold the two components tightly together and using a soldering gun with a flat tip, melt the material securing the components together. Do not over heat the affected area, damage to the exterior of the trim panel may occur.
    b. If the heat staked material is broken or missing, use a hot glue gun to apply new material to the area to be repaired. The panels that are being heat staked must be held together while the applying the glue. Once the new material is in place, it may be necessary to use a soldering gun to melt the newly applied material. Do not over heat the affected area, damage to the exterior of the trim panel may occur.
4. Allow the repaired area to cool and verify the repair.
5. Install trim panel.

BUZZ, SQUEAKS AND RATTLES

Buzz, Squeaks and Rattles (BSR's) may be caused by any one or more of the following and may be corrected as indicated:

- Loose fasteners should be tightened to specifications.
- Damaged or missing clips should be replaced.
- Damaged trim panels should be replaced.
- Incorrectly installed trim panels should be reinstalled properly.

Many BSR complaints such as loose trim, can be serviced using various tapes or lubricants. Tapes including foam, flock and anti-squeak, can be used to eliminate noises caused by metal, plastic and vinyl components. Long life lubricants and greases can also be used on a variety of components. Refer to the **BUZZ, SQUEAKS AND RATTLES** table for materials and usage.

BUZZ, SQUEAKS AND RATTLES

ITEM	FEATURES	APPLICATIONS	SERVICE TEMP
ITCH AND SQUEAK TAPE	An abrasion resistant material thin enough to conform to most irregular surfaces. Stops most itches and squeaks.	Between metal and metal, metal and plastic, metal and vinyl, vinyl and plastic. Interior. Examples: Trim panels and bezels.	-40° to 107° C (-40° to 225° F)
BLACK NYLON FLOCK	Nylon Flock with an aggressive acrylic adhesive. Provides for cushioning and compression fit, also isolates components. Water-resistant.	Between metal and metal, metal and plastic, vinyl and plastic. Examples: Pull cups, bezels, clips, ducts, top cover to glass, cowl panel.	-40° to 82° C (-40° to 180° F)
HIGH DENSITY URETHANE FOAM	Tear resistant, highly resilient and durable.	Between metal and metal, metal and plastic. Water-resistant. Examples: I/P, heavy metal rattles, isolating brackets.	-40° to 82° C (-40° to 180° F)
OPEN CELL FOAM TAPE	Soft foam conforms to irregular surfaces.	Wire harness and connector wrap. Examples: Seals, gasket, wiring, heat ducts.	-40° to 82° C (-40° to 180° F)
CLOSED CELL LOW DENSITY FOAM TAPE	Soft, conformable. Water-resistant.	Wherever bulk is needed. Prevents closing flutters and rattles when applied to door watershield. Examples: Door, I/P.	-40° to 82° C (-40° to 180° F)
NYE® GREASE 880	Long life.	Suspensions. Examples: Strut bushings, sway bars.	-40° to 200° C (-40° to 390° F)
KRYTOX® OIL	Long life. Will not dry out or harm plastics or rubber.	When access is not possible, oil will migrate to condition. Vinyl, rubber, plastic, metal. Examples: Convertible top bushings, pull cups trim panel inserts.	-34° to 205° C (-30° to 400° F)
KRYTOX® GREASE	Long life. Will not dry out or harm plastics or rubber.	Vinyl, rubber, plastic, metal, glass. Examples: Weather-strips, backlite and windshield moldings.	-34° to 205° C (-30° to

USE OF HEAT DURING REPAIR

WARNING:

Chrysler Group LLC engineering's position on the use of heat during collision repair is as follows:

- **Any body panel or frame component damaged which is to be repaired and reused, must be repaired using the "cold straightening" method. No heat may be used during the straightening process.**
- **During rough straightening prior to panel replacement, damaged panels or frame components may be heated to assist in body/frame realignment. The application of heat must be constrained to the parts which will be replaced and not allowed to affect any other components.**

This "no heat" recommendation is due to the extensive use of high strength and advanced high strength steels in Chrysler Group LLC products. High-strength materials can be substantially and negatively affected from heat input which will not be obviously known to the repairer or consumer.

Ignoring these recommendations may lead to serious compromises in the ability to protect occupants in a future collision event, reduce the engineered qualities and attributes, or decrease the durability and reliability of the vehicle.

This statement supersedes any previously released information by the Chrysler Group LLC.

Failure to follow these instructions may result in serious or fatal injury.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

WARNINGS

WARNING: **Use an Occupational Safety and Health Administration (OSHA) approved breathing filter, when spraying paint or solvents in a confined area. Failure to follow these instructions may result in possible serious or fatal injury.**

- **avoid prolonged skin contact with petroleum or alcohol based cleaning solvents.**
- **do not stand under a hoisted vehicle that is not properly supported on safety stands. Failure to follow these instructions may result in possible serious or fatal injury.**

CAUTION: **When holes are drilled or punched in an inner body panel, verify the depth of space to the outer body panel, electrical wiring or other components. Damage to the vehicle can result.**

- **do not weld exterior panels unless combustible material on the interior of vehicle is removed from the repair area. Fire or hazardous conditions, can result.**
- **always have a fire extinguisher ready for use when welding.**
- **disconnect the negative (-) cable clamp from the battery when servicing electrical components that are live when the ignition is off. Damage to electrical system can result.**
- **do not use abrasive chemicals or compounds on painted surfaces. Damage to finish can result.**
- **do not use harsh alkaline based cleaning solvents on painted or upholstered surfaces. Damage to finish or color can result.**
- **do not hammer or pound on plastic trim panel when servicing interior trim. Plastic panels can break.**

Restraint Warnings

WARNING: **To avoid potential physical injury, or damage to sensitive electronic circuits and systems, always disconnect and isolate the battery negative (ground) cable and the positive cable, then ground the positive cable to discharge the ORC capacitor before performing any welding operations on the vehicle. Failure to take the proper precautions could result in accidental airbag deployment, possible damage to the Supplemental Restraint System (SRS) circuits and components, and possible damage to other electronic circuits and components. Whenever a welding process is being performed within 30 cm (12 in) of an electronic module/harness, then that module/harness should be relocated out of the way, or disconnected. Always protect against component or vehicle damage from weld spatter by using weld blankets and screens. Failure to follow these instructions may result in serious or fatal injury.**

WARNING: **To avoid serious or fatal injury on vehicles equipped with the Supplemental Restraint System (SRS), never attempt to repair the electrically conductive circuits or wiring components related to the SRS for which there is no MOPAR wiring repair kit. It is important to use ONLY the recommended splicing kit and procedure. For applicable and available MOPAR wiring repair kits, please visit the MOPAR Connector Web Site at the following address on the internet: (http://dto.vftis.com/mopar/disclaimer.asp). Inappropriate repairs can compromise the conductivity and current carrying capacity of those critical electrical circuits, which may cause SRS components not to deploy when required, or to deploy when not required. Only minor cuts or abrasions of wire and terminal insulation where the conductive material has not been damaged, or connector insulators where the integrity of the latching and locking mechanisms have not been compromised may be repaired using appropriate methods.**

WARNING: **To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.**

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, Occupant Classification System (OCS), seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to follow these instructions may result in accidental airbag deployment.**

WARNING:

To avoid potential physical injury or damage to sensitive electronic circuits and systems, always disconnect and isolate the battery negative (ground) cable and the positive cable, then ground the positive cable to discharge the Occupant Restraint Controller (ORC) capacitor before performing any welding operations on the vehicle. Failure to take the proper precautions could result in accidental airbag deployment, possible damage to the Supplemental Restraint System (SRS) circuits and components, and possible damage to other electronic circuits and components. Whenever a welding process is being performed within 12 inches (30 centimeters) of an electronic module or wiring harness, then that module or harness should be relocated out of the way, or disconnected. Always protect against component or vehicle damage from weld spatter by using weld blankets and screens.

WARNING:

To avoid serious or fatal injury, do not attempt to dismantle an airbag unit or tamper with its inflator. Do not puncture, incinerate or bring into contact with electricity. Do not store at temperatures exceeding 93° C (200° F). An airbag inflator unit may contain sodium azide and potassium nitrate. These materials are poisonous and extremely flammable. Contact with acid, water, or heavy metals may produce harmful and irritating gases (sodium hydroxide is formed in the presence of moisture) or combustible compounds. An airbag inflator unit may also contain a gas canister pressurized to over 17.24 kPa (2500 psi). Failure to follow these instructions may result in possible serious or fatal injury.

WARNING:

To avoid serious or fatal injury when handling a seat belt tensioner retractor. Exercise proper care to keep fingers out from under the retractor cover and away from the seat belt webbing where it exits from the retractor cover. Failure to follow these instructions may result in possible serious or fatal injury.

WARNING:

To avoid serious or fatal injury, replace all Supplemental Restraint System (SRS) components only with parts specified in the Chrysler Mopar® Parts Catalog. Substitute parts may appear interchangeable, but internal differences may result in inferior occupant protection.

WARNING:

To avoid serious or fatal injury, the fasteners, screws, and bolts originally used for the Supplemental Restraint System (SRS) components must never be replaced with any substitutes. These fasteners have special coatings and are specifically designed for the SRS. Anytime a new fastener is needed, replace it with the correct fasteners provided in the service package or specified in the Chrysler Mopar® Parts Catalog.

WARNING:

To avoid serious or fatal injury when a steering column has an airbag unit attached, never place the column on the floor or any other surface with the steering wheel or airbag unit face down. Failure to follow these instructions may result in possible serious or fatal injury.

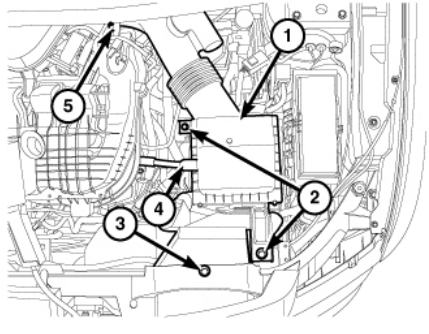
INSTALLATION

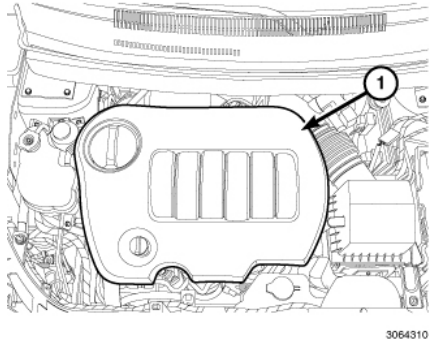
Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Engage the air inlet hose to the resonator and install the air cleaner body (1) with two bolts (2) tightened to 9 N·m (80 in. lbs.).
2. Tighten the air inlet hose to resonator clamp (5) to 4 N·m (35 in. lbs.).
3. Install the push pin (3).
4. Install the fresh air makeup hose (4) to the air cleaner body.



3064341

5. Install the engine cover (1).
6. Connect the negative battery cable and tighten nut to 5 N·m (45 in. lbs.).



3064310

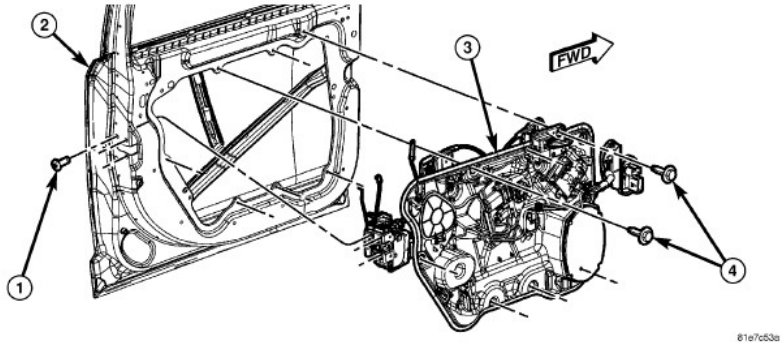
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure



1. Position the carrier plate (3) into the door (2).
2. Install the carrier plate mounting fasteners (4) and tighten to 6 N·m (53 in. lbs.).
3. Install the door latch fasteners (1) and tighten to 7 N·m (62 in. lbs.).
4. Install the fastener that is behind the door handle on the exterior of the door and tighten to 7 N·m (62 in. lbs.).
5. Connect the exterior door handle connecting rods.
6. Install the wiring harness to the carrier plate and connect all electrical connectors.
7. Install the exterior handle. (Refer to 23 - Body/Door - Front/HANDLE, Exterior/Installation)
8. Install the front door window. (Refer to 23 - Body/Door - Front/GLASS, Door - Installation) .
9. Install the door trim panel. (Refer to 23 - Body/Door - Front/PANEL, Door Trim - Installation)

Fuel Delivery: | **Fuel:**

ADJUSTMENTS

1. Align door to achieve equal spacing to surrounding body panels.
2. Panels should be flush across all gaps (Refer to 23 - Body/Body Structure/Gap and Flush - Specifications) .
3. If door needs to be adjusted Fore/Aft loosen A-pillar to hinge bolts.
4. If door needs to be adjusted In/Out loosen door to hinge nuts.
5. If in/out alignment can not be achieved, it may be necessary to enlarge (drill) the hinge/door flange holes to 12.5 mm (1/2 inch) maximum.
6. This may allow extra movement to achieve the proper alignment.
7. Remove door and hinge as necessary.

2014 Dodge JC - DODGE JOURNEY

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

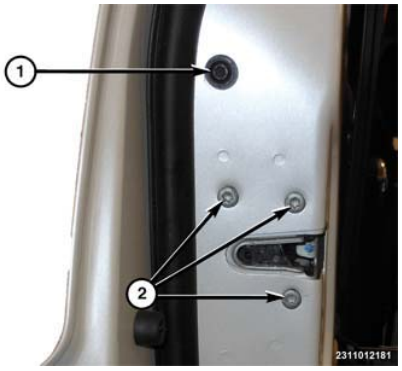
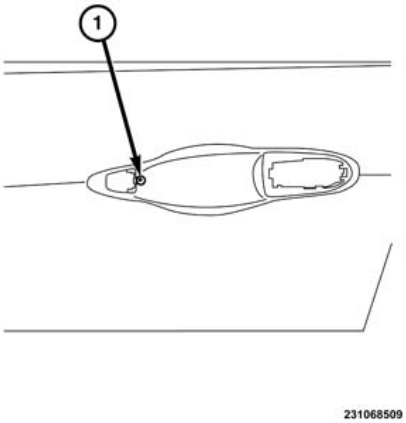
1. Position the carrier plate near the door and connect the door latch wiring connector.
2. Carefully install the carrier plate by inserting the door handle bracket and latch into the rear of the door and tuck the regulator behind the upper door.
3. Slide the carrier plate rearward into position.
4. Fasten the five carrier plate mounting clips (4) by turning 1/4 turn.
5. Install the six carrier plate fasteners (2) and tighten to 6 N·m (53 in. lbs).
6. Connect the electrical connectors on the exterior of the carrier plate and install the harness (3) routing clips and onto tabs.

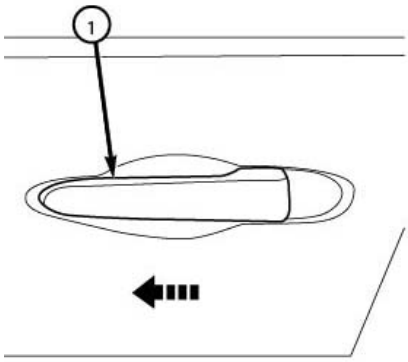


7. Install the door latch fasteners (2) and tighten to 8 N·m (71 in. lbs).
8. Position the outer door handle bracket and install the fastener (1) and tighten to 6 N·m (53 in. lbs).



9. Install the door handle bracket fastener (1) located in the exterior door handle pocket and tighten securely.

10. Install the exterior door handle, (Refer to 23 - Body/Doors - Rear/HANDLE, Exterior/Installation)

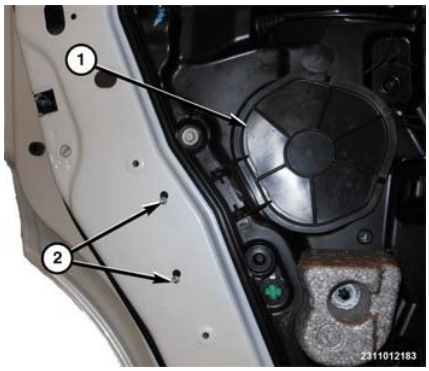


231068511

11. Position the lower glass channel into the door.

12. Tighten the rear lower glass channel fasteners (2) securely.

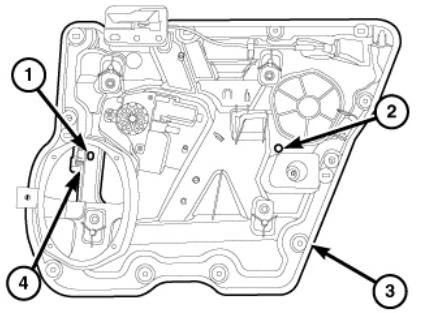
13. Close the access door (1) fully.



14. Release the tape securing the glass in the up position

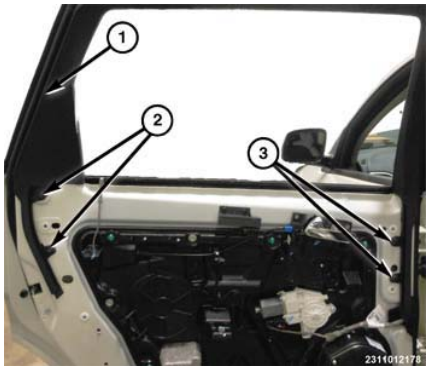
15. Lower the glass down into regulator and firmly push down until the tabs snap into place .

16. Instal the door speaker, (Refer to 08 - Electrical/8A - Audio and Video/SPEAKER/Installation)



17. Insert the window surround moulding (1) into the window opening.

18. Install the push pin fasteners (2 and 3).



19. Install the door trim panel. (Refer to 23 - Body/Doors - Rear/PANEL, Rear Door Trim - Installation) .

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

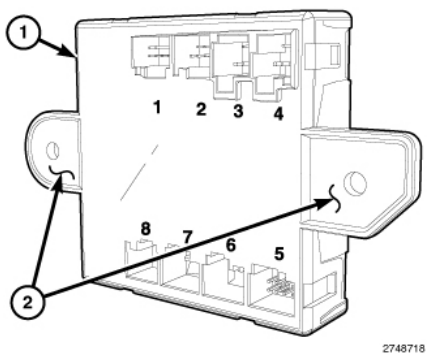
DESCRIPTION

This vehicle is equipped with two electronic front door control modules (1) (also known as a Driver Door Module/DDM, a Passenger Door Module/PDM or Front Door Multiplex/MUX Modules), one each on both the driver and passenger front doors. Each door control module is concealed behind the front door trim panel where it is secured through two integral mounting tabs (2) to the door hardware module carrier by two screws. The front door control modules are located in the upper front corner of the front door hardware carriers, just below the mirror flag area of the front door.

Each door control module contains a microprocessor and is connected to the various switches on that door. In the case of the driver side module, it communicates with some switches over a Local Interface Network (LIN) data bus. Both the driver and passenger side module also receive various hard wired switch inputs and provide numerous hard wired outputs to various devices located on their respective doors. In addition, both front door control modules communicate with each other and with other electronic modules in the vehicle over the Controller Area Network (CAN) Interior High Speed (IHS) data bus system.



Concealed and protected within the molded plastic door control module housing is the printed circuit board and the other electronic circuitry of the module. The front door control modules are connected to the vehicle electrical system through up to eight connector receptacles that are integral to the module housing.

A door control module cannot be adjusted or repaired and, if damaged or ineffective, it must be replaced. The door control module software is flash programmable.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

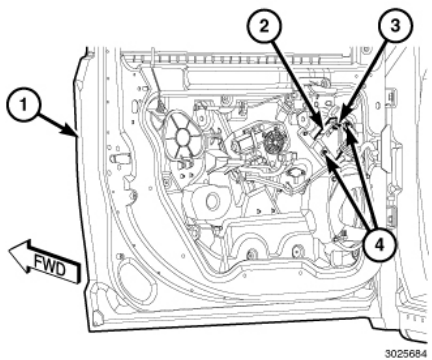
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure



1. Position the door control module (2) to the front door hardware module carrier.
2. Install and tighten the two screws (4) that secure the door control module to the front door hardware module carrier. Tighten the screws securely.
3. Reconnect each of the electrical connectors (3) to the connector receptacles of the door control module.
4. Reinstall the trim panel to the inside of the front door (1). (Refer to 23 - Body/Door - Front/PANEL, Door Trim - Installation) .
5. Reconnect the battery negative cable.
6. The Manual Relearn procedure should be performed following service of a door control module so that the module can learn the correct hard stops of the power window regulator. (Refer to 08 - Electrical/8N - Power Systems/Power Windows - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The microprocessor-based electronic front door control modules (also known as a Driver Door Module/DDM, a Passenger Door Module/PDM or Front Door Multiplex/MUX Modules) contain logic circuits that monitor various hard wired low current, multiplexed inputs from the power window, power lock, power mirror and memory switches on their respective door. They also receive Controller Area Network (CAN) Interior High Speed (IHS) data bus electronic message-based external inputs from the opposing front door control module as well as from other electronic modules in the vehicle. The front door control modules also monitor hard wired power window motor Hall effect sensors and memory mirror position sensor inputs.

In addition, the front door control module on the driver side front door receives electronic message inputs from the driver side front door switch module over the Local Interface Network (LIN) data bus network. The program logic within the front door control module allows the microprocessor to prioritize all of these inputs and determine the tasks it needs to perform. These tasks are then completed either by controlling hard wired outputs to the various motors, actuators or lamps on its own or the rear doors, or by sending electronic message requests over the CAN-IHS bus to the appropriate electronic module in the vehicle.

The front door control modules are powered by a fused B(+) circuit and are grounded at all times so that they can operate regardless of the ignition switch position. Both driver and passenger door control modules provide active and stored Diagnostic Trouble Codes (DTC) through On-Board Diagnostics (OBD) and communicate with a diagnostic scan tool using the CAN data bus.

The hard wired inputs and outputs of the front door control module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between modules and other devices that provide some features of the power window, power lock, memory, interior lighting or exterior lighting system features the front door control modules provide. The most reliable, efficient and accurate means to diagnose the front door control modules or the electronic controls and communication related to operation of these systems requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

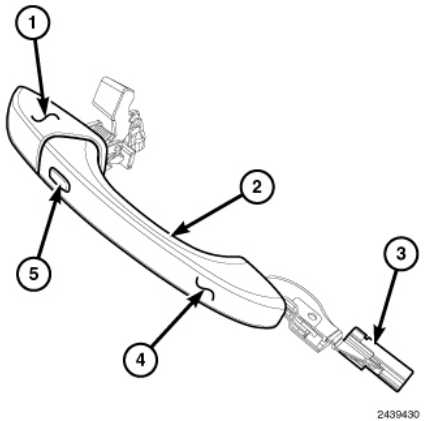
DESCRIPTION

Vehicles equipped with the optional Passive Entry (PE) system have unique outside front door handles that incorporate three switches and a logic circuit. These unique PE door handles are sometimes referred to as smart handles. The handle itself is very similar in appearance to those used in conventional non-PE applications, consisting primarily of a grip (4) and a base (1).

The PE door handles can be readily identified by a tactile, resistive membrane lock switch (5) located on the outward facing vertical surface at the rearward end of the handle grip, and by a capacitive sensor or switch membrane patch on the inside surface (2) of the grip. A third, Hall-effect type switch as well as an Integrated Circuit (IC) chip are concealed within the grip near the handle base.

The mechanical functions and mounting provisions of the PE handle are identical to those of a conventional outside door handle. However, an integral connector receptacle (3) is located at the forward end of the handle grip where it is concealed within the door interior. The PE handle is connected to the vehicle electrical system through a dedicated take out and connector of the PE door jumper wire harness.

The individual switches of the PE outside front door handles cannot be adjusted or repaired. If any one of the switches, the IC or any of the mechanical handle components is damaged or ineffective, the entire handle unit must be replaced. (Refer to 23 - Body/Door - Front/HANDLE - Removal) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The three switches of each Passive Entry (PE) outside front door handle are powered by and provide a direct input to the Integrated Circuit (IC) of that door handle. The IC of each PE outside front door handle receives power from the Radio Frequency Hub (also known as the RF Hub) on a signal circuit, and a clean ground from the RF Hub on a return circuit. The PE handle IC and the RF Hub communicate with each other by modulating the current in the signal circuit.

Each PE outside front door handle has three switches. The inputs from those three switches and the handle logic circuit allow each handle to send the RF Hub up to four different signals: Unlock Request, Hall, Lock Request and Error. The RF Hub determines the system response based upon the inputs it receives from each handle as well as the inputs it receives through the authentication process with each detected FOB with Integrated Key (FOBIK).

The tactile, mechanical, resistive membrane lock switch allows the user to actively lock the vehicle. The capacitive switch senses a hand approaching the handle grip to passively unlock the vehicle. The Hall-effect switch senses handle grip movement. An adaptation algorithm in the logic circuit of each handle can modify the sensitivity of the capacitive switches as well as system responses to the Hall-effect switch inputs to compensate for sensed repeated or continuous actuations such as might be caused by the switch membrane being wetted, but restores normal sensitivity about one minute after the repeated or continuous actuation input ceases.

The hard wired inputs and outputs of the PE outside front door handle may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, the most reliable, efficient and accurate means to diagnose this component requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Power operated front door, rear door and liftgate locking mechanisms are standard equipment in this vehicle. The lock mechanisms of each door and liftgate latch are actuated by a reversible electric motor integral to each latch unit. A connector receptacle integral to each latch connects the power lock motor and the integral door or liftgate ajar micro switch to the vehicle electrical system through a dedicated take out and connector of the door or liftgate wire harness.

The power lock motors cannot be adjusted or repaired and, if ineffective or damaged, the entire door or liftgate latch unit must be replaced.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The power lock motors are controlled by outputs received from the Body Control Module (BCM) (also known as the Common Body Controller/CBC). The BCM acts upon programming as well as electronic **lock** or **unlock** command message inputs received over the Controller Area Network (CAN) data bus from the driver or passenger door modules indicating the power lock switch status, or from the Radio Frequency Hub (also known as the RF Hub) based upon inputs from the Remote Keyless Entry (RKE) transmitters or, on vehicles so equipped, from the Passive Entry (PE) system door handle switches.

A positive and negative battery connection to the two lock motor terminals will cause the motor to move in one direction, locking or unlocking the latch. Reversing the current will cause the motor to move in the opposite direction.

The power lock motors and the hard wired circuits between the motors and the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the power lock system or the electronic controls or communication between other modules and devices that provide some features of the power lock system. The most reliable, efficient, and accurate means to diagnose the power lock motors or the electronic controls and communication related to power lock motor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

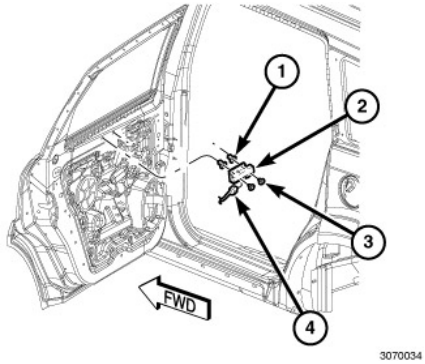
1. Check to be certain that the two plastic nuts (1) are in good condition and properly installed in the rear door.
2. Position the Low Frequency (LF) antenna (2) to the rear door.
3. Install and tighten the two screws (3) that secure the LF antenna to the two plastic nuts in the rear door. Tighten the screws securely.
4. Reconnect the wire harness connector (4) to the connector receptacle for the LF antenna.



5. Reinstall the trim panel onto the inside of the rear door. (Refer to 23 - Body/Doors - Rear/PANEL, Rear Door Trim - Installation) .
6. Reconnect the battery negative cable.

DOOR MODULE LEARN PROCEDURES

NOTE:

- This procedure must be performed anytime the power window system has been serviced in either front door or when there is a possible concern with a door module calibration.
- The battery must be fully charged or the vehicle running before proceeding with the learn procedure.
- All doors must be completely closed before proceeding.
- It is suggested to sit inside the vehicle in the drivers seat and close the door.

Express-up / Express-down possible concerns.

- Glass will not lower all the way down flush to the belt-line.
- Glass will not raise fully; wind noise / water leak.
- Glass will not raise automatically (Expess-up) after lifting the switch to the second detent and releasing.

To relearn the door module memory after module replacement, perform the following procedure:

1. Check and repair any door module Diagnostic Trouble Code (DTC)(s) unrelated to missing calibration before proceeding.
2. Using the window switch, lower the door glass to the full-down position by pushing down (depress) the window switch to its second detent and hold the switch until the door glass is fully open. Continue to hold the window switch down for two seconds after the door glass is fully open.
3. Raise the door glass to the full-up position by pulling up on the window switch and hold the switch until the door glass is fully closed. Continue to hold the window switch up for two seconds after the door glass is full closed.
4. Code should now be stored. Clear code and test window operations.

To relearn the door module memory after window/regulator replacement, perform the following procedure:

1. Using the scan tool, go to the network topology screen.
2. Click on the Diagnostic Procedures tab at the lower portion of the screen.
3. Run ECU Reset for DDM/PDM.
4. DDM/PDM calibration missing DTC will now set.
5. Using the window switch, lower the door glass to the full-down position by pushing down (depress) the window switch to its second detent and hold the switch until the door glass is fully open. Continue to hold the window switch down for two seconds after the door glass is fully open.
6. Raise the door glass to the full-up position by pulling up on the window switch and hold the switch until the door glass is fully closed. Continue to hold the window switch up for two seconds after the door glass is full closed.

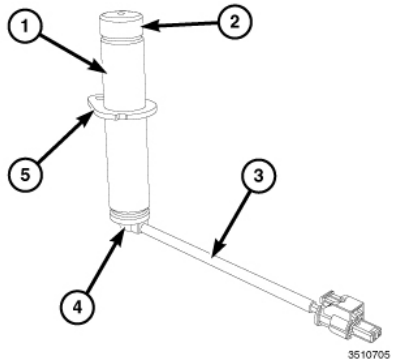
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Active hood hinge actuators are found only in vehicles equipped with the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or Active Hood System), which is available only in vehicles manufactured for certain export markets. An EPP active hood hinge actuator is located on each hinge. The actuators are secured by a self-tapping screw through an integral bracket (5) to a mounting plate integral to the rear of the lower bracket on each active hood hinge.

The actuator consists primarily of a tubular metal housing (1) containing a metal piston (2) with a molded plastic cap and a small pyrotechnically activated gas generator (4). The actuators are controlled by the Electronic Pedestrian Protection Module (EPPM). An actuator pigtail wire (3) and connector insulator are routed to a dedicated take out of the headlamp and dash wire harness and connected to the vehicle electrical system by a keyed and latching molded plastic connector insulator to ensure a secure connection.



The EPP active hood hinge actuators cannot be repaired and, if ineffective or damaged, the entire actuator unit must be replaced. The actuators are not intended for reuse and must be replaced following any EPP system deployment.

INSTALLATION

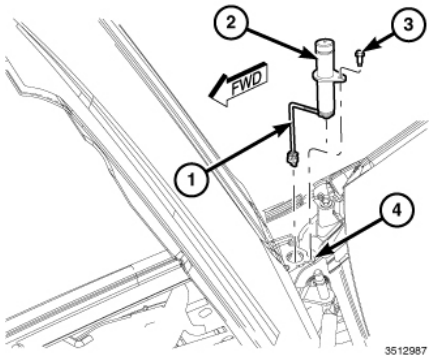
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

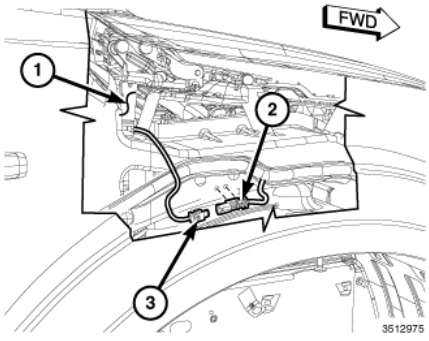
To avoid serious or fatal injury on vehicles equipped with the Electronic Pedestrian Protection (EPP) system, disable the system before attempting any EPP system component diagnosis or service. With the ignition switch in the OFF position, disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the EPP system. Failure to take the proper precautions could result in accidental active hood hinge actuator deployment.

NOTE:

The following procedure is for replacement of an ineffective or damaged Electronic Pedestrian Protection (EPP) system active hood hinge actuator. If the actuator is ineffective or damaged, but not deployed, it should be handled in the same manner as is used when handling non-deployed supplemental restraints. Review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the actuator has been deployed, review the recommended procedures for Service After A Pedestrian Protection Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Guide the pigtail wire (1) and connector of the Electronic Pedestrian Protection (EPP) active hood hinge actuator (2) through the mount (4) at the back of the hood hinge lower bracket while positioning the actuator to the hinge.
2. Align the hole in the actuator bracket with the hole in the hinge mount.
3. Install and tighten the screw (3) that secures the actuator to the hinge. Tighten the screw to 7.9 N·m (70 in. lbs.).
4. Reconnect the pigtail wire connector (3) of the actuator (1) to the headlamp and dash wire harness connector (2).
5. Reinstall the splash shield into the right or left front wheel house. (Refer to 23 - Body/Exterior /SHIELD, Splash - Installation) .
6. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any EPP system component. (Refer to 10 - Restraints - Standard Procedure) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Electronic Pedestrian Protection (EPP) active hood hinge actuators are deployed by a signal generated by the Electronic Pedestrian Protection Module (EPPM) through the right and left hood actuator line 1 and line 2 (or squib) circuits. When the EPPM sends the proper electrical signal to the actuators, the electrical energy generates enough heat to initiate a small pyrotechnic gas generator.

The gas generator is installed in one end of a steel cylinder tube where the piston is sealed to the inside circumference of the tube. As the gas expands, it pushes the piston up the tube, where it actuates the leveraging mechanism of the active hood hinge that cuts the hinge shear rivet and raises the rear edge of the hood panel.

Raising the hood panel following a frontal impact of the vehicle creates additional clearance between the hood and the hard components within the engine compartment. This clearance helps to reduce the severity of injuries that a pedestrian might experience in these situations as a result of harmful contact with those hard parts found just beneath the hood panel within the engine compartment.

The EPPM monitors the condition of the active hood hinge actuators through circuit resistance, and will register a Diagnostic Trouble Code (DTC) for any fault that is detected. The Occupant Restraint Controller (ORC) continually monitors the EPPM and when the EPPM registers a DTC, the ORC will request illumination of the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC). Proper diagnosis of the active hood hinge actuator gas generator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

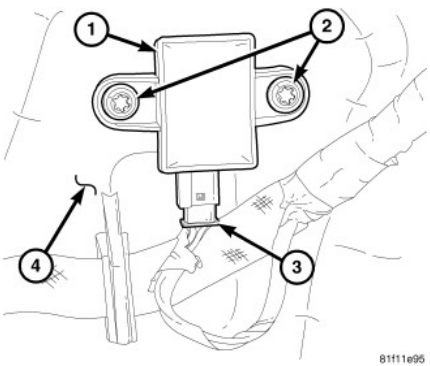
SIDE - FRONT DOOR

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, never strike or drop the side impact sensor, as it can damage the impact sensor or affect its calibration. The side impact sensor enables the system to deploy the side Supplemental Restraint System (SRS) components. If an impact sensor is accidentally dropped during service, the sensor must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper side SRS component deployment.**

NOTE: Be certain that the gasket between the pressure-type side impact sensor and the front door module carrier panel is in good condition and positioned on the back of the sensor. There MUST be a good seal between the sensor and the module carrier panel for the sensor to operate properly. If the gasket is in poor condition, replace the sensor.



1. Position the side impact sensor (1) to the right or left front door module carrier panel (4). When the sensor is correctly positioned, the arrow on the sensor label will be pointed toward the bottom of the door.
2. Install and tighten the two screws (2) that secure the side impact sensor to the door. Tighten the screws to 2.4 N·m (21 in. lbs.).
3. Reconnect the front door wire harness connector (3) to the sensor connector receptacle.
4. Reinstall the trim panel onto the inside of the right or left front door. (Refer to 23 - Body/Door - Front/PANEL, Door Trim - Installation) .
5. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

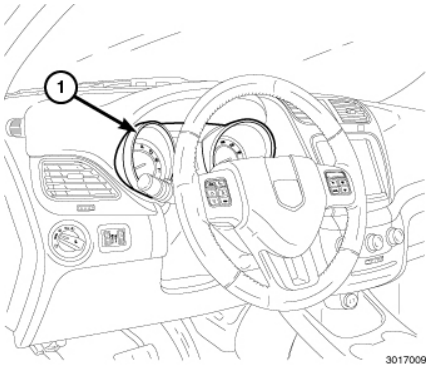
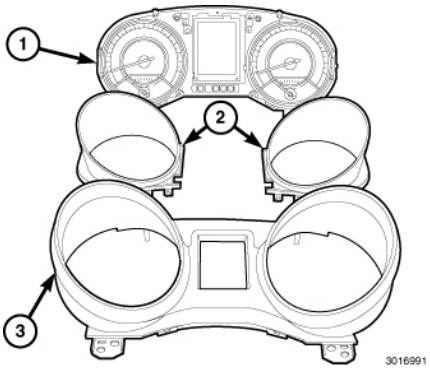
DESCRIPTION

The instrument cluster (IC) (1) for this vehicle is located directly in front of the driver, above the steering column opening. The mounts and the electrical connections, are concealed within the instrument panel behind various trim panels and the cluster itself. The IC contains various indicators, analog gauges, a Thin Film Transistor (TFT) display unit and an integrated circuit board. The TFT displays odometer information, automatic transmission gear selector position (PRNDL) and several indicators, some of which are market, model or equipment dependent.

The IC also contains the standard equipment Electronic Vehicle Information Center (EVIC). The EVIC provides the outside ambient temperature, compass headings, average fuel economy, elapsed time, numerous textual warning messages, reminder indicators and certain diagnostic information.



The IC can be serviced as several components. The gauges, indicators and electronic circuitry along with the housing itself are only serviced as an assembly and cannot be adjusted or repaired. If a gauge, Light Emitting Diode (LED) unit, the TFT, electronic circuit board, circuit board hardware, cluster overlay or cluster housing is damaged or ineffective, the entire unit must be replaced. The cluster lenses, hood and mask are available for separate service replacement.



VEHICLE SYSTEMS SUPPORT

AUDIBLE WARNINGS

The IC electronic circuit board is equipped with a piezoelectric speaker and programming that allows it to provide various audible alerts to the vehicle operator. These alerts include single chime tones and continuous slow or fast tones. An IC can also produce audible clicks that are used to emulate the sound of a conventional turn signal or hazard warning flasher.

FUEL LEVEL DATA

The IC receives a message from the Body Control Module (BCM) over the Control Area Network (CAN) data bus. The IC uses this information to calculate the proper fuel gauge needle position and to control low fuel indicator operation.

VEHICLE WARNING MESSAGES

When the appropriate conditions exist, messages such as **DOOR** (door ajar), **GATE**(liftgate ajar), **LOCOOL** (low engine coolant), **LOWASH** (low washer fluid), **ESC OFF** (Electronic Stability Control in partial off mode), **NOBUS** (data bus communication fault) or **CHANGE OIL** appear in the TFT display.

CHANGE OIL MESSAGE

Your vehicle is equipped with an engine oil change indicator system. The **CHANGE OIL** message flashes in place of the IC odometer value for approximately 12 seconds after a single chime has sounded to indicate the next scheduled oil change interval. The engine oil change indicator system is duty cycle based, which means the engine oil change interval may fluctuate dependent upon your personal driving style.

Unless reset, this message continues to display each time you turn the ignition switch to the ON position. To turn off the message temporarily, press and release the appropriate push button in the Electronic Vehicle Information Center (EVIC) switch pod in the left horizontal spoke of the steering wheel to restore the odometer value display. To reset the oil change indicator system, (after performing the scheduled maintenance) perform the following procedure:

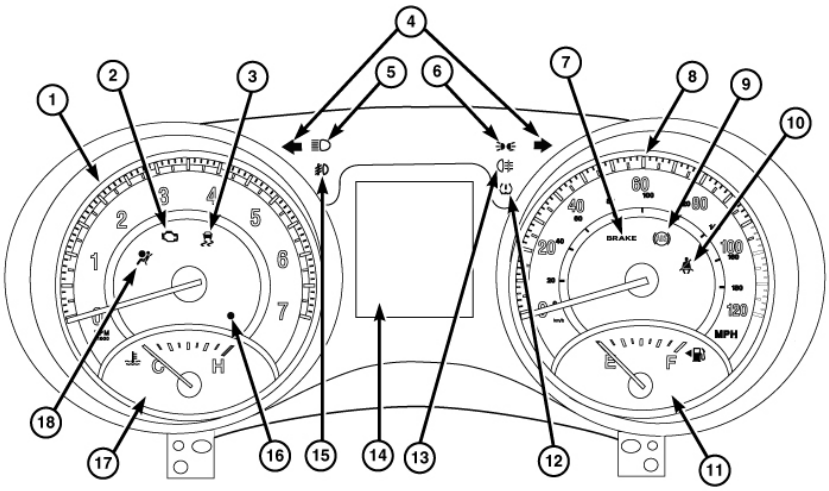
1. Turn the ignition switch to the ON position. (Do not start the engine).
2. Fully press the accelerator pedal slowly three times within 10 seconds.
3. Turn the ignition switch to the LOCK position.

NOTE: If the indicator message illuminates when you start the vehicle, the oil change indicator system did not reset. If necessary, repeat this procedure

ELECTRONIC VEHICLE INFORMATION CENTER DISPLAY

The Electronic Vehicle Information Center (EVIC) system conveniently allows the driver to select a variety of useful information by pressing the appropriate buttons of the EVIC switch pod, which is located in the left horizontal spoke of the steering wheel. The EVIC displays information related to the following:

- **Compass display**
- **Outside temperature display**
- **System status**
- **Trip computer functions**
- **Vehicle information warning message displays**



3010041

The EVIC display (14) consists of a Thin Film Transistor (TFT) unit soldered to the electronic circuit board and is located between the tachometer on the left and the speedometer on the right.

The odometer value display is located within the TFT and is visible through a window in the cluster overlay with a smoked lens. The dark lens prevents the display from being clearly visible when it is not illuminated. The odometer information is stored in the IC memory. This information can be increased when the proper inputs are provided, but the information cannot be decreased. The odometer can display values up to 999,999 kilometers (999,999 miles). The odometer latches at these values, and will not roll over to zero.

The odometer display does not show leading zeroes, does not have a decimal point and will not show values less than a full unit (kilometer or mile). The unit of measure (**MPH** or **km/h**) for the odometer display is shown in the TFT in the same white color and at the same lighting level as the odometer values. The unit of measure for the odometer can be selected using the customer programmable features function of the Integrated Center Stack (ICS) screen module. The odometer has a RENTAL CAR mode, which will illuminate the odometer information in the EVIC whenever either front door is opened while the status of the ignition switch is OFF or ACCESSORY.

During daylight hours (exterior lamps are OFF) the TFT is illuminated at full brightness for clear visibility. At night (exterior lamps are ON), the TFT lighting level is adjusted with the other cluster general illumination lighting using the panel lamps dimmer function of the interior lighting control. However, a PARADE mode position of the control allows the TFT to be illuminated at full brightness if the exterior lamps are turned ON during daylight hours.

Dual trip odometer (Trip A and Trip B) capability is standard equipment on this vehicle. Both trip odometers appear within the TFT display unit. The trip odometer

information is stored in the IC memory. Each trip odometer can display values up to 16099.9 kilometers (9999.9 miles). Each trip odometer will roll over to zero independently when it accumulates these values. The trip odometer minimum value is **0.0** (miles or kilometers) and does have a decimal point to show values in tenths of a full unit (miles or kilometers).

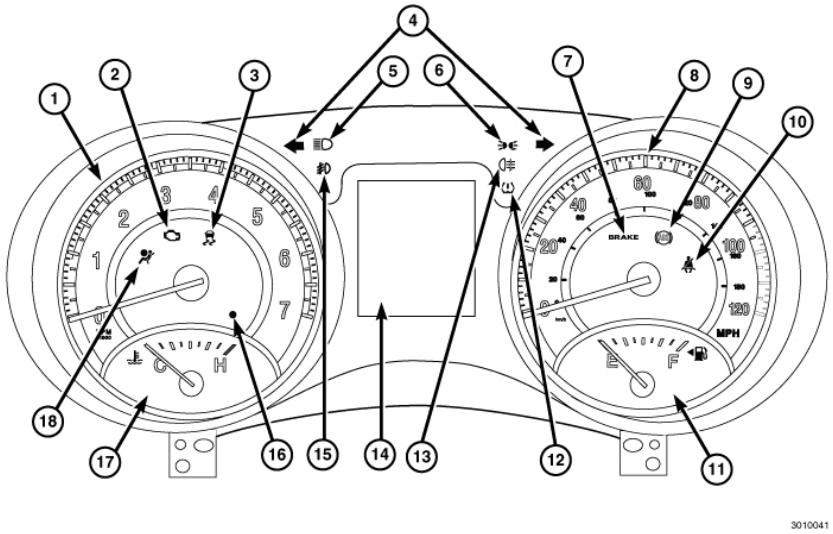
The unit of measure (**MPH** or **km/h**) for the trip odometer display is shown next to the **Trip A** or **Trip B** text in the TFT in the same white color and at the same lighting level as the trip odometer values. The unit of measure for the trip odometer can be selected using the customer programmable features function of the Integrated Center Stack (ICS) screen module.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The instrument cluster (IC) assembly houses 4 analog gauges standard on all models and, has provisions for up to 13 International Control and Display Symbol icon indicators that are all controlled by the IC. For more information on the icon indicators, (Refer to 08 - Electrical/8J - Instrument Cluster/INDICATORS, Instrument Cluster - Description) . The gauge graphics are white against a black field except for the two red graduations at the high end of the gauge scale on the engine temperature gauge, and the low end on the gauge scale on the fuel level gauge. The tachometer has several red graduations at the high end of the gauge scale that designate the red line area, making them clearly visible within the instrument cluster in daylight.



The instrument cluster includes the following analog gauges:

- **Engine Temperature Gauge (17)**
- **Fuel Gauge (11)**
- **Speedometer (8)**
- **Tachometer (1)**

ENGINE TEMPERATURE

The standard equipment engine temperature gauge is located in the lower quadrant of the tachometer. The gauge consists of a movable gauge needle or pointer controlled by the IC circuitry and a fixed 90 degree gauge scale on the cluster overlay that reads left-to-right from **C** (or Cold) to **H** (or Hot). for all vehicles. An International Control and Display Symbol icon for **Engine Coolant Temperature** is located on the cluster overlay, on the left side of the gauge. (Refer to 00 - Vehicle Data/Vehicle Information/International Vehicle Control and Display Symbols - Description) for more information.

FUEL LEVEL

A fuel gauge is standard equipment on all instrument clusters. This gauge is located in the lower quadrant of the speedometer. Similar to the engine temperature gauge, the fuel level gauge consists of a movable gauge needle or pointer controlled by the IC circuitry and a fixed 90 degree gauge scale on the cluster overlay that reads left-to-right from **E** (or Empty) to **F** (or Full). The International Control and Display Symbol icon for **Fuel** is located on the cluster overlay, on the right side of the gauge. An arrowhead pointed to the left side of the vehicle is imprinted on the cluster overlay next to the **Fuel** icon on the gauge to provide the driver with a reminder as to the location of the fuel filler access.

SPEEDOMETER

Standard equipment on all instrument clusters, the speedometer is located to the right of center in the instrument cluster. The speedometer consists of a movable gauge needle or pointer controlled by the instrument cluster circuitry and a fixed 210 degree primary scale on the gauge dial face. For all vehicles the speedometer reads left-to-right either from **0** to **120** or **140** mph, or from **0** to **220** or **240** km/h, depending upon the market for which the vehicle is manufactured. Each version also has a secondary inner scale on the gauge dial face that provides the equivalent opposite units from the primary scale. On all vehicles, text appearing on the cluster overlay above the hub of the speedometer needle abbreviates the unit of measure for the primary scale (either **MPH** or **km/h**), and text inside the low end of the secondary scale indicates the

unit of measure for that scale.

TACHOMETER

The standard equipment tachometer is located to the left of center in the instrument cluster. The tachometer consists of a movable gauge needle or pointer controlled by the instrument cluster circuitry and a fixed 210 degree scale. On all gasoline engine vehicles, the tachometer reads left-to-right from **0** to **7**. On all diesel engine vehicles, the tachometer reads left-to-right from **0** to **6**. The text **RPM X 1000** imprinted on the cluster overlay directly above the hub of the tachometer needle. This text identifies that each number on the tachometer scale is to be multiplied by 1000 rpm.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

GAUGES

All gauges receive battery current through the Instrument Cluster (IC) circuitry; only when the ignition switch is in the ON or START positions. With the ignition switch in the OFF position the cluster circuitry is programmed to move all of the gauge needles back to the low end of their respective scales. Therefore, the gauges do not accurately indicate any vehicle condition unless the ignition switch is in the ON or START positions.

All of the gauges are driven by stepper motors. Two fixed electromagnetic coils are located within each gauge. These coils are wrapped at right angles to each other around a movable permanent magnet. The movable magnet is suspended within the coils on one end of a pivot shaft, while the gauge needle is attached to the other end of the shaft. One of the coils has a fixed current flowing through it to maintain a constant magnetic field strength. Current flow through the second coil changes, which causes changes in its magnetic field strength. The current flowing through the second coil is changed by the cluster circuitry in response to messages received over the CAN data bus from the Body Control Module (BCM). The gauge needle moves as the movable permanent magnet aligns itself to the changing magnetic fields created around it by the electromagnets.

The gauges are diagnosed using the IC self-diagnostic test. Each time the cluster is put through the self test, the engine coolant temperature gauge needle will be swept to several calibration points on the gauge scale in a prescribed sequence in order to confirm the functionality of the gauge and the cluster control circuitry. (Refer to 08 - Electrical/8J - Instrument Cluster - Diagnosis and Testing) for more information. Proper testing of the CAN data bus and the electronic data bus message inputs to the IC that control each gauge require the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

ENGINE TEMPERATURE

The engine temperature gauge gives an indication to the vehicle operator of the engine operating temperature. This gauge is controlled by the IC based upon programming and electronic messages received from the Engine Control Module (ECM) over the CAN data bus.

The engine coolant temperature gauge stepper motor receives battery current on the cluster electronic circuit board through the fused ignition switch output (run-start) circuit whenever the ignition switch is in the ON or START positions. The gauge needle is moved back to the low end of the scale after the ignition switch is turned to the Off position. The IC controls the gauge needle position and provides the following features:

- **Engine Temperature Message** - Each time the IC receives an electronic **engine temperature** message from the ECM indicating the temperature is between the low end of normal [about 41 °C (105 °F) for gasoline engines, or about 28 °C (82 °F) for diesel engines] and the high end of normal [about 124 °C (255 °F) for gasoline engines, or about 118 °C (244 °F) for diesel engines], the gauge needle is moved to the actual relative temperature position on the gauge scale.
- **Engine Temperature Low Message** - Each time the ECM receives an electronic **engine temperature** message from the ECM indicating the temperature is low [at or below about 40 °C (104 °F) for gasoline engines, or about 27 °C (81 °F) for diesel engines], the gauge needle is held below the graduation on the far left end of the gauge scale. The gauge needle remains below the low end of the gauge scale until the IC receives a message from the ECM indicating that the temperature is above the low end of normal, or until the ignition switch is turned to the OFF position, whichever occurs first.
- **Engine Temperature High** - Each time the IC receives an electronic **engine temperature** message from the ECM indicating the temperature is high [at or above about 127 °C (261 °F) for gasoline engines, or about 118 °C (244 °F) for diesel engines], the gauge needle is moved to the red graduation at the high end of the gauge scale, the engine temperature indicator is illuminated and a single chime tone is sounded. The gauge needle remains at the red graduation and the engine temperature indicator remains illuminated until the IC receives a message from the ECM indicating that the temperature is below about 124 °C (255 °F) for gasoline engines, or about 115 °C (239 °F) for diesel engines, or until the ignition switch is turned to the OFF position, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the engine temperature indicator is cycled OFF and then ON again by the appropriate messages from the ECM.
- **Engine Temperature Critical Message** - Each time the IC receives an electronic **engine temperature** message from the ECM indicating the temperature is critical [above about 132 °C (270 °F)], the gauge needle is held at the red **H** graduation at the high end of the gauge scale and a check gauges indicator textual warning is displayed in the re-configurable dot matrix display. The gauge needle remains at the red **H** graduation until the cluster receives a message from the PCM indicating that the temperature is below critical [about 127 °C (261 °F)], or until the ignition switch is turned to the OFF position, whichever occurs first.
- **Communication Error** - If the IC fails to receive an **engine temperature** message, it will hold the gauge needle at the last indication for about five seconds or until the ignition switch is turned to the OFF position, whichever occurs first. After five seconds, the IC will move the gauge needle to the low end of the gauge scale.

The ECM continually monitors the engine coolant temperature sensor to determine the engine operating temperature. The ECM then sends the proper engine coolant temperature messages to the IC. For further diagnosis of the engine coolant temperature gauge or the IC circuitry that controls the gauge, (Refer to 08 - Electrical/8J - Instrument Cluster - Diagnosis and Testing) . If the IC turns on the engine temperature indicator due to a high engine temperature gauge reading, it may indicate that the engine or the engine cooling system requires service. The engine coolant temperature gauge is serviced as a unit with the instrument cluster.

FUEL GAUGE

The fuel gauge gives an indication to the vehicle operator of the level of fuel in the fuel tank. This gauge is controlled by the IC circuit board based upon programming and a hard-wired input received from the fuel level sending unit on the fuel pump module in the fuel tank.

The fuel gauge is a stepper motor design gauge that receives battery current on the IC electronic circuit board through the fused ignition switch output (run-start) circuit whenever the ignition switch is in the On or Start positions. The IC is programmed to move the gauge needle back to the low end of the scale after the ignition switch is turned to the Off position. The IC circuitry controls the gauge needle position and provides the following features:

- **Fuel Level Message** - The Body Control Module (BCM) provides a constant current source to the fuel level sending unit and monitors a return input on a fuel level sense circuit. The resistance through the fuel level sending unit increases as the fuel level rises and decreases as the fuel level falls causing changes in the fuel level sense input voltage. The BCM then sends the appropriate electronic **fuel level** messages to the IC. The IC programming applies an algorithm to calculate the

proper fuel gauge needle position based upon the fuel level message input, then moves the gauge needle to the proper relative position on the gauge scale. This algorithm is used to dampen gauge needle movement against the negative effect that fuel sloshing within the fuel tank can have on accurate inputs from the fuel tank sending unit to the BCM.

- **Less Than 11 Percent Tank Full Message** - Each time the fuel level message to the IC indicates the fuel tank is about 11 percent full or less for 10 consecutive seconds and the vehicle speed is zero, or for 60 consecutive seconds and the vehicle speed is greater than zero, the gauge needle is moved to about the one-sixteenth graduation on the gauge scale, the low fuel indicator is illuminated, and a single chime tone is sounded. The low fuel indicator remains illuminated until the fuel level message indicates that the fuel tank is greater than about 14 percent full for 10 consecutive seconds and the vehicle speed is zero, or for 60 consecutive seconds and the vehicle speed is greater than zero, or until the ignition switch is turned to the OFF position, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the low fuel indicator is cycled OFF and then ON again by the appropriate messages from the BCM.
- **Less Than Empty Stop Message** - Each time the IC receives a fuel level message indicating the fuel level in the fuel tank is less than the **E** (or Empty) gauge needle stop position for five consecutive seconds, the gauge needle is moved to the low end of the gauge scale and the low fuel indicator is illuminated immediately. This input would indicate that the fuel level sense input to the BCM is a short circuit.
- **More Than Full Stop Message** - Each time the IC receives a fuel level message indicating the fuel level in the fuel tank is more than the **F** (or Full) gauge needle stop position for five consecutive seconds, the gauge needle is moved to the low end of the gauge scale and the low fuel indicator is illuminated immediately. This input would indicate that the fuel level sense input to the BCM is an open circuit.

The BCM continually monitors the fuel tank sending unit to determine the level of fuel in the fuel tank. The BCM then sends the proper fuel level messages to other electronic modules in the vehicle over the CAN data bus. For further diagnosis of the fuel gauge or the IC circuitry that controls the gauge, (Refer to 08 - Electrical/8J - Instrument Cluster - Diagnosis and Testing) . The fuel gauge is serviced as a unit with the instrument cluster.

SPEEDOMETER

The speedometer gives an indication to the vehicle operator of the vehicle road speed. This gauge is controlled by the IC circuit board based upon programming and electronic messages received from the BCM. The BCM is provided the vehicle speed information across the CAN data bus by either the ECM, the Electronic Stability Control (ESC) module or the Anti-lock Brake System (ABS) module.

The IC circuitry controls the gauge needle position and provides the following features:

- **Vehicle Speed Message** - Each time the ECM receives an electronic **vehicle speed** message from the ECM it will calculate the correct vehicle speed reading and position the gauge needle at that relative speed position on the gauge scale. The IC will receive a new message and reposition the gauge pointer accordingly about every 88 milliseconds. The gauge needle will continually be positioned at the relative vehicle speed position on the gauge scale until the vehicle stops moving, or until the ignition switch is turned to the OFF position, whichever occurs first.
- **Communication Error** - If the IC fails to receive a speed message, it will hold the gauge needle at the last indication for about three seconds, or until the ignition switch is turned to the OFF position, whichever occurs first. After three seconds, the gauge needle will return to the left end of the gauge scale.

The ECM continually monitors the vehicle speed sensor to determine the vehicle road speed. The ECM then sends the proper vehicle speed messages to the IC. For further diagnosis of the speedometer or the IC circuitry that controls the gauge, (Refer to 08 - Electrical/8J - Instrument Cluster - Diagnosis and Testing) . The speedometer is serviced as a unit with the instrument cluster.

TACHOMETER

The tachometer gives an indication to the vehicle operator of the engine speed. This gauge is controlled by the IC circuit board based upon programming and electronic messages received from the ECM over the CAN data bus.

The tachometer is a stepper motor design gauge that receives battery current on the IC electronic circuit board through the fused ignition switch output (run-start) circuit whenever the ignition switch is in the ON or START positions. The IC is programmed to move the gauge needle back to the low end of the scale after the ignition switch is turned to the OFF position. The IC circuitry controls the gauge needle position and provides the following features:

- **Engine Speed Message** - Each time the IC receives an electronic **engine speed** message from the ECM it will calculate the correct engine speed reading and position the gauge needle at that relative speed position on the gauge scale. The IC will receive a new message and reposition the gauge pointer accordingly about every 88 milliseconds. The gauge needle will continually be repositioned at the relative engine speed position on the gauge scale until the engine stops running, or until the ignition switch is turned to the OFF position, whichever occurs first.
- **Communication Error** - If the IC fails to receive a speed message, it will hold the gauge needle at the last indication for about three seconds, or until the ignition switch is turned to the OFF position, whichever occurs first. After three seconds, the gauge needle will return to the left end of the gauge scale.

The ECM continually monitors the crankshaft position sensor to determine the engine speed. The ECM then sends the proper engine speed messages to the IC. The tachometer is serviced as a unit with the instrument cluster.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

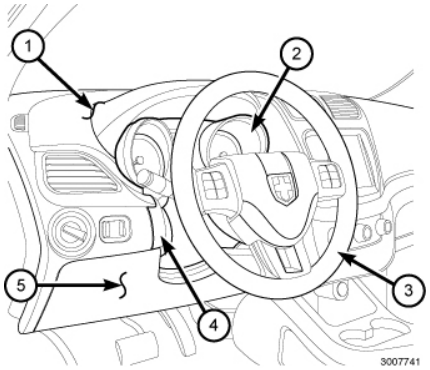
WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CLUSTER ASSEMBLY

1. Install the instrument cluster in the instrument panel.
2. Connect and the negative battery cable.

CLUSTER ASSEMBLY

NOTE: If the cluster has been replaced, the replacement cluster should be programmed with the correct mileage. Verfiy the correct mileage via WiTech/Scan Tool.

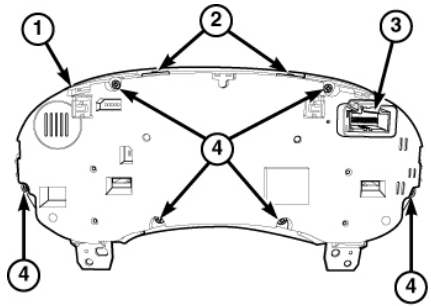


1. Position the instrument cluster assembly (2) in the instrument panel (1) and connect the electrical connector.
2. Align the upper retaining clips to the instrument panel; press firmly and evenly and engage the clips.
3. Install the two lower fasteners and tighten securely.
4. Position the steering column seal into place, and press firmly and evenly and engage the clips.
5. Install the kneeblocker (Refer to 23 - Body/Instrument Panel/KNEEBLOCKER/Installation) .
6. Connect the battery negative cable.

CLUSTER MASK, HOOD AND LENS

NOTE:

The lens assemblies for this vehicle can be serviced separately from side to side.



3007762

1. Position the lens and hood assembly onto the instrument cluster housing (1).
2. Press firmly and evenly to engage the integrated latches to secure the assembly to the cluster housing.
3. Position the instrument cluster mask onto the face of the instrument cluster housing.
4. Working around the perimeter of the cluster housing, engage the integrated latches (2) on the cluster mask assembly.
5. Install the six fasteners (4) that secure the mask to the cluster housing.

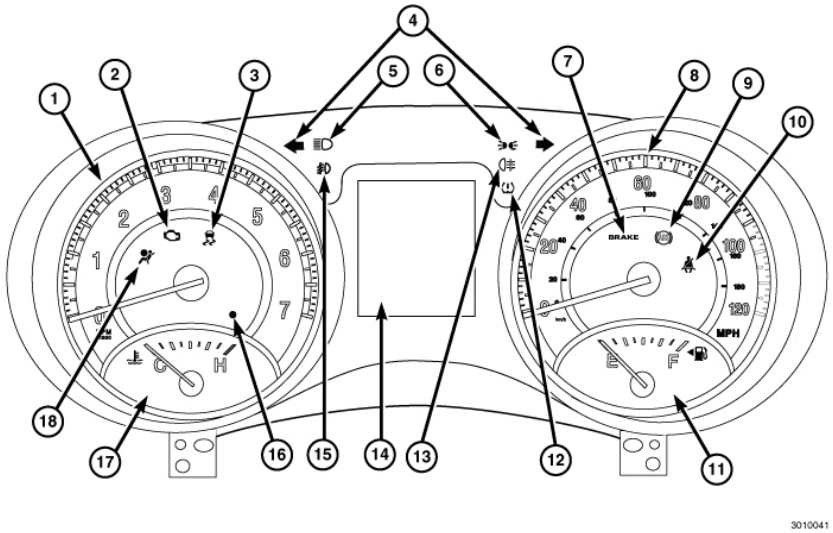
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The Instrument Cluster (IC) assembly has provisions for up to 19 International Control and Display Symbol icon indicators that are all controlled by the IC. Some of the indicators are automatically configured when the IC is connected to the vehicle electrical system for compatibility with certain optional equipment or equipment required for regulatory purposes in certain markets. While each IC may have provisions for indicators to support every available option, the configurable indicators will not function in vehicles that do not have the equipment that an indicator supports.

A dedicated Light Emitting Diode (LED) soldered onto the circuit board illuminates each indicator in the IC, except those within an electronic display unit. Several dimmable LED units illuminate each gauge dial face for visibility when the exterior lighting is turned ON. These LED units are not available for service replacement and, if damaged or ineffective, the entire IC must be replaced.



The instrument cluster includes provisions for the following ISO icon indicators:

- **Airbag Indicator (18)**
- **Antilock Brake System (ABS) Indicator (9)**
- **Brake Indicator (7)**
- **Electronic Stability Control (ESC) Indicator (3)**
- **ESC OFF Indicator (14)** - textual message in the Thin Film Transistor (TFT) display.
- **Front Fog Lamp Indicator (15)**
- **High Beam Indicator (5)**
- **Low Fuel Indicator (14)** - icon in the TFT display.
- **Malfunction Indicator Lamp (MIL) (2)**
- **Position Lamp Indicator (6)**
- **Rear Fog Lamp Indicator (13)** - in markets where rear fog lamps are available only.
- **Seat Belt Indicator (10)**
- **Security Indicator (16)**
- **Tire Pressure Monitor (TPM) Indicator (12)**
- **Turn Signal (Right and Left) Indicators (5)**

Many systems and features found in this vehicle display messages or icons within the TFT (14). The IC includes provisions for the following ISO icon indicators or textual messages within this display:

- **Change Oil Indicator** - icon in the TFT display.
- **Check Gauges Indicator** - textual message in TFT display.
- **Coolant Low Indicator** - icon in the TFT display.
- **Cruise Indicator** - textual message in the TFT display.

- **Electronic Throttle Control (ETC) Indicator** - icon in the TFT display.
- **Gas Cap Indicator** - icon in the TFT display.
- **Low Brake Fluid Level Indicator** - textual message in TFT display.
- **No Bus Indicator** - textual message in TFT display.
- **Odometer** - in TFT display.
- **Park Assist Disabled Indicator** - icon in the TFT display.
- **Power Liftgate Indicator** - an icon in the TFT display.
- **Remote Start Indicator** - textual message in TFT display.
- **Service Park Assist System Indicator** - textual message in TFT display.
- **Transmission Overtemp Indicator** - icon in the TFT display.
- **Turn-Signal-On Reminder Indicator** - textual message in TFT display.
- **Washer Fluid Indicator** - icon in the TFT display.
- **Wait-To-Start Indicator** - icon in the TFT display (diesel engines only).
- **Water-In-Fuel Indicator** - icon in the TFT display (diesel engines only).

For more information on the International Control and Display Symbol icons, (Refer to 00 - Vehicle Data/Vehicle Information/International Vehicle Control and Display Symbols - Description) .

Each indicator in the IC, except those located within an electronic display unit, is illuminated by a dedicated Light Emitting Diode (LED) unit that is soldered onto the IC electronic circuit board. Cluster illumination is accomplished by several dimmable LED units, which illuminate each of the gauge dial faces for visibility when the exterior lighting is turned ON. These LED units are serviced only as a complete unit with the IC and, if damaged or ineffective, the entire IC assembly must be replaced. The cluster lens and the cluster hood and mask unit are the only components of the IC that can be serviced separately.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

Indicators are located in various locations within the Instrument Cluster (IC) and are all connected to the electronic circuit board. All of the indicators are completely controlled by the IC. The various indicators are controlled by different strategies; some receive fused ignition output from the IC circuitry and have a switched ground, while others are grounded through the IC circuitry and have a switched battery feed. However, most are controlled by (CAN) or Local Interface Network (LIN) data bus messages from other electronic modules in the vehicle while others are controlled by a combination of hard wired inputs, electronic messaging and IC programming. If the IC loses CAN data bus communication, the IC circuitry will automatically turn ON the Malfunction Indicator Lamp (MIL) until CAN data bus communication is restored.

In addition, certain indicators in this IC are automatically or self-configured. This feature allows the configurable indicators to be enabled by the IC circuitry for compatibility with certain optional equipment. These indicators are enabled or disabled by an electronic **configuration** message sent to the IC by the Body Control Module (BCM) (also known as the Common Body Controller/CBC). The BCM defaults for the Antilock Brake System (ABS) and the airbag indicators is enabled. These configuration settings must be programmatically disabled in the BCM using a diagnostic scan tool for vehicles that do not have this equipment. The automatically or self-configured indicators remain latent in the IC at all times and will be active only when the IC receives the appropriate CAN or LIN bus message inputs for that optional system or equipment.

The hard-wired indicator inputs may be diagnosed using conventional diagnostic tools and procedures. However, the IC circuitry and electronic CAN or LIN data bus message controlled indicators are diagnosed using the self-diagnostic IC **Self test**. (Refer to 08 - Electrical/8J - Instrument Cluster - Diagnosis and Testing) for more information. For proper testing of the CAN or LIN data bus and the electronic data bus message inputs to the IC that control each indicator requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

Below are brief explanations of the indicators available on this vehicle. More detailed information may be available elsewhere in this service information, located within the section covering the system or component that control or influence the illumination of that indicator. The indicators, the TFT display, the LED units as well as the gauges are only serviceable with the IC as an assembly. The cluster lenses and the hood and mask assembly may be serviced separately from the IC.

ABS INDICATOR

The ABS indicator gives an indication to the vehicle operator when the ABS system, or a circuit or component of the system is ineffective. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the cluster from the CAB over the CAN data bus. The IC will illuminate the ABS indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The ABS indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the status of the ignition switch is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the ABS indicator for the following reasons:

- **ABS Indicator Lamp-On Message** - Each time the IC receives an electronic **ABS indicator lamp-ON** message from the CAB, the ABS indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **Communication Error** - If the IC receives no lamp-ON or lamp-OFF messages from the CAB for five consecutive message cycles, the ABS indicator is illuminated. The indicator remains illuminated until the IC receives a valid message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **ABS Diagnostic Test** - The ABS indicator is blinked ON and OFF by lamp-ON and lamp-OFF messages from the CAB during the performance of the ABS diagnostic tests.

The CAB continually monitors the ABS circuits and sensors to decide whether the system is in good operating condition. The CAB then sends the proper lamp-ON or lamp-OFF message to the IC. If the CAB sends a lamp-ON message after the bulb test, it indicates that the CAB has detected a system malfunction or that the ABS system has become ineffective. The CAB will store a DTC for any malfunction it detects. Each time the ABS indicator fails to light due to an open or short in the IC ABS indicator circuit, the IC sends a message notifying the CAB of the condition, then the IC and the CAB will each store a DTC and the IC will flash the brake indicator ON and OFF as a backup to notify the vehicle operator.

For proper diagnosis of the anti-lock brake system, the CAB, the IC, the CAN data bus or the electronic communication related to ABS indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

AIRBAG INDICATOR

The airbag indicator gives an indication to the vehicle operator when the airbag system, or a circuit or component of the system is ineffective. The airbag indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the Occupant Restraint Controller (ORC) over the CAN data bus. The IC will illuminate the airbag indicator for about six seconds as a bulb test each time the ignition switch status transitions to ON.

The airbag indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the airbag indicator for the following reasons:

- **Airbag Indicator Lamp-On Message** - Each time the IC receives an electronic **airbag indicator lamp-ON** message from the ORC, the airbag indicator will be illuminated. The indicator remains illuminated for about 12 seconds or until the IC receives a lamp-OFF message from the ORC, whichever is longer. This indicator will also be extinguished when the ignition switch status transitions to OFF.
- **Communication Error** - If the IC receives no lamp-ON or lamp-OFF messages from the ORC for 10 consecutive message cycles, the airbag indicator is illuminated. The indicator remains illuminated until the IC receives a single lamp-OFF message from the ORC.

The ORC continually monitors the airbag system circuits and sensors to decide whether the system is in good operating condition. The ORC then sends the proper lamp-ON or lamp-OFF message to the IC. If the ORC sends a lamp-ON message after the bulb test, it indicates that the ORC has detected a system malfunction or that the airbags and seat belt tensioners may not deploy when required, or may deploy when not required. The ORC will store a DTC for any malfunction it detects. Each time the

airbag indicator fails to illuminate due to an open or short in the IC airbag indicator circuit, the IC sends a message notifying the ORC of the condition, then the IC and the ORC will each store a DTC.

For proper diagnosis of the airbag system, the ORC, the IC, the CAN data bus or the electronic communication related to airbag indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

AJAR INDICATORS

The ajar indicators give an indication to the vehicle operator that one or more of the passenger compartment doors or the liftgate may be open or not completely latched. These indicators are controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the Body Control Module (BCM) over the CAN data bus. The BCM monitors hard-wired inputs from the door and liftgate ajar switches.

The ajar indicator function of the TFT electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused B(+) circuit. Therefore, the ajar indications can occur regardless of the ignition switch position. The IC will turn ON an ajar indicator for the following reasons:

- **Ajar Indicator Lamp-On Message** - Each time the IC receives an electronic **door ajar indicator lamp-on** or **liftgate ajar indicator lamp-on** message from the BCM indicating that a door or the liftgate or a combination of these is open or not completely latched, the appropriate ajar textual message and icons will be illuminated. If the IC detects a vehicle speed input greater than zero (kilometers or miles-per-hour) while the ignition switch status is ON or START, the ajar indication will be accompanied by a single chime tone. When the ignition switch status is anything except ON or START, any and all ajar indications will time out after about five minutes.

The ajar switches on the door and liftgate latch mechanisms provide hard-wired ground inputs to the BCM circuitry through the ajar switch sense circuits whenever a door or the liftgate is open or not completely latched. The BCM continually monitors the door and liftgate ajar switches to determine the status of the doors and liftgate, then sends the proper electronic **ajar indicator lamp-on** or **lamp-off** message to the IC.

The hard wired ajar switch inputs to the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. For proper diagnosis of the BCM, the IC, the CAN data bus or the electronic communication related to ajar indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

BRAKE/PARK BRAKE INDICATOR

The brake indicator gives an indication to the vehicle operator when the parking brake is applied, when there are certain brake hydraulic system malfunctions as indicated by a low brake hydraulic fluid level condition or when the brake fluid level switch is disconnected. The brake indicator can also give an indication when certain faults are detected in the Antilock Brake System (ABS). This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the CAB or the Body Control Module (BCM) over the CAN data bus. The BCM monitors the hard wired input from the park brake switch. The IC will illuminate the brake indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The brake indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the brake indicator for the following reasons:

- **Brake Indicator Lamp-On Message** - Each time the IC receives an electronic **brake indicator lamp-ON** message from the CAB, the brake indicator will be illuminated. The CAB may also send lamp-ON messages as feedback during ABS diagnostic procedures. The indicator remains illuminated until the IC receives a lamp-OFF message from the CAB or until the ignition switch status transitions to OFF, whichever occurs first.
- **Low Brake Fluid Textual Warning Message** - When the CAB detects a low brake fluid level input from the brake fluid level switch, it will send an electronic **textual warning request** message requesting the IC display a textual warning message. Each time the IC receives this message from the CAB, a **LOW BRAKE FLUID LEVEL** textual message will appear within the IC electronic display to accompany brake indicator illumination. This message indicates that the CAB has detected a low brake fluid level condition in the brake master cylinder or that there is a problem in the brake fluid level switch or circuits.
- **Park Brake Switch Input** - Each time the IC receives an electronic **brake indicator lamp-FLASH** message from the BCM, the brake indicator will be flashed ON and OFF. While the ignition switch status is ON, the BCM monitors the park brake switch through the park brake switch sense circuit (park brake switch closed = park brake applied or not fully released). The indicator continues to flash until the park brake switch sense input to the BCM is an open circuit (park brake switch open = park brake fully released), or until the ignition switch status transitions to OFF, whichever occurs first.
- **Antilock Brake System (ABS) Indicator Backup** - If the IC detects a fault in the ABS indicator circuit it will send a message indicating the fault to the CAB, then flash the brake indicator ON and OFF. The IC will continue to flash the brake indicator until the ABS indicator circuit fault is resolved, or until the ignition switch status transitions to OFF, whichever occurs first.

The park brake switch on the park brake lever mechanism provides a hard-wired ground input to the BCM circuitry through the park brake switch sense circuit whenever the park brake is applied or not fully released. The CAB continually monitors the ABS system circuits and sensors, including the brake fluid level switch on the brake master cylinder reservoir, to decide whether the system is in good operating condition. The CAB then sends the proper lamp-ON, lamp-OFF or lamp-FLASH message to the IC. If the CAB sends a lamp-ON message after the bulb test, it indicates that the CAB has detected a brake hydraulic system malfunction or that the ABS system has become ineffective. The CAB will store a DTC for any malfunction it detects.

The hard wired park brake switch input to the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. For proper diagnosis of the brake fluid level switch, the ABS, the BCM, the CAB, the IC, the CAN data bus or the electronic communication related to brake indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CHANGE OIL INDICATOR

The change oil indicator gives an indication to the vehicle operator when a duty-cycle algorithm contained within the software of the PCM determines that a recommended oil change interval has been attained. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The change oil indicator function of the IC electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the change oil indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the change oil indicator for the following reasons:

- **Change Oil Indicator Lamp-On Message** - Each time the ignition switch status transitions to ON and the IC receives an electronic **change oil indicator lamp-**

ON message from the PCM indicating that a duty-cycle based recommended oil change interval has been attained, the change oil indicator will be illuminated for about ten seconds, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first.

- **Change Oil Indicator Reset Procedure** - Once an engine oil change has been completed, the PCM duty cycle counters can be reset using the following procedure. Set the ignition switch status to ON, but DO NOT start the engine. Slowly depress and release the accelerator pedal fully three times within ten seconds. The IC will display a textual **OIL CHANGE RESET** message. Set the ignition switch status to OFF. If the change oil indicator illuminates the next time the engine is started, repeat this procedure.

The PCM continually monitors numerous sensor inputs to determine the duty-cycles to which the engine is being subjected. A pre-programmed algorithm within the PCM then determines when to send the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the change oil indicator, the PCM, the IC, the CAN data bus or the electronic communication related to change oil indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CHARGING INDICATOR

The charging indicator gives an indication to the vehicle operator when the electrical system voltage is too low or too high. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus. The IC will illuminate the charge indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The charging indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the charging indicator for the following reasons:

- **Voltage Low Message** - Each time the IC receives an electronic **system voltage** message from the PCM indicating the voltage is low (less than about 11.5 volts is a charge fail condition), the charging indicator will be illuminated. The indicator remains illuminated until the IC receives a message from the PCM indicating the voltage is normal (greater than about 12.0 volts, but less than 16.0 volts), or until the ignition switch status transitions to OFF, whichever occurs first.
- **Voltage High Message** - Each time the IC receives an electronic **system voltage** message from the PCM indicating the voltage is high (greater than about 16.0 volts), the charging indicator will be illuminated. The indicator remains illuminated until the IC receives a message from the PCM indicating the voltage is normal (less than about 15.5 volts, but greater than 11.5 volts), or until the ignition switch status transitions to OFF, whichever occurs first.

The PCM continually monitors the electrical system voltage to control the generator output. The PCM then sends the proper messages to the IC. If the IC turns ON the charging indicator due to a charge fail or voltage high condition, it may indicate that the charging system requires service.

For proper diagnosis of the charging system, the PCM, the IC, the CAN data bus or the electronic communication related to charging indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CHECK GAUGES INDICATOR

The check gauges indicator gives an indication to the vehicle operator when the engine coolant temperature gauge indicates the coolant temperature is high or critical. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The check gauges indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the check gauges indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the check gauges indicator for the following reasons:

- **Engine Temperature High or Critical Message** - Each time the IC receives an electronic **engine coolant temperature** message from the PCM indicating the temperature is high or critical the engine coolant temperature gauge needle is moved to the appropriate position at the high end of the gauge scale, the check gauges textual warning is displayed, and a single chime tone is sounded. The check gauges textual warning remains illuminated until the IC receives a message from the PCM indicating that the temperature is below the high end of normal, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the check gauges textual warning is cycled OFF and then ON again by the appropriate temperature messages from the PCM.

The PCM continually monitors the engine coolant temperature sensor to determine the engine operating temperature. The PCM then sends the proper messages to the IC. If the IC turns on the check gauges indicator due to a high or critical engine temperature gauge reading, it may indicate that the engine or the engine cooling system requires service.

For proper diagnosis of the engine coolant temperature sensor, the PCM, the IC, the CAN data bus or the electronic communication related to check gauges indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CRUISE INDICATOR

The cruise indicator gives the vehicle operator an indication when the speed control system is ON, regardless of whether the speed control is engaged. This indicator is controlled by the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus.

The cruise indicator LED is completely controlled by the IC logic circuit, and that logic only allows this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED is always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the cruise indicator for the following reasons:

- **Cruise Indicator Lamp-On Message** - Each time the IC receives an electronic **cruise indicator lamp-on** message from the PCM indicating the speed control system is ON, the cruise indicator is illuminated. The indicator remains illuminated until the IC receives a lamp-off message from the PCM, or until the ignition switch status transitions to OFF, whichever occurs first.

The PCM continually monitors the speed control switches to determine the appropriate outputs to control the vehicle speed. The PCM then sends the proper lamp-on or lamp-off message to the IC.

For proper diagnosis of the speed control switches, the PCM, the IC, the CAN data bus or the electronic communication related to cruise indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

ELECTRONIC THROTTLE CONTROL INDICATOR

The Electronic Throttle Control (ETC) indicator gives an indication to the vehicle operator when the ETC system, or a circuit or component of the system is ineffective. The ETC indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus. The IC will illuminate the ETC indicator for about fifteen seconds as a bulb test each time the ignition switch status transitions to ON.

The ETC indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the ETC indicator for the following reasons:

- **ETC Indicator Lamp-On Message** - Each time the IC receives an electronic **ETC indicator lamp-ON** message from the PCM, the ETC indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the PCM message. The indicator remains illuminated solid or continues to flash for about 12 seconds or until the IC receives a lamp-OFF message from the PCM, whichever is longer. If the indicator is illuminated solid with the engine running the vehicle will usually remain drivable. If the indicator is flashing with the engine running the vehicle may require towing. A flashing indicator means the ETC system requires immediate service. The indicator will be extinguished when the ignition switch status transitions to OFF.

The PCM continually monitors the ETC system circuits and sensors to decide whether the system is in good operating condition. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the PCM sends a lamp-ON message after the bulb test, it indicates that the PCM has detected an ETC system malfunction or that the ETC system is ineffective. The PCM will store a DTC for any malfunction it detects. Each time the ETC indicator fails to illuminate due to an open or short in the IC ETC indicator circuit, the IC sends a message notifying the PCM of the condition, then the IC and the PCM will each store a DTC.

For proper diagnosis of the ETC system, the PCM, the IC, the CAN data bus or the electronic communication related to ETC indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

ENGINE TEMPERATURE INDICATOR

The engine temperature indicator gives an indication to the vehicle operator when the engine temperature gauge reading reflects a condition requiring immediate attention. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received from the PCM over the CAN data bus. The IC will illuminate the engine temperature indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The engine temperature indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The engine temperature indicator will also be turned ON for the following reasons:

- **Engine Temperature High Message** - Each time the IC receives a message from the PCM indicating the engine coolant temperature is high, the engine temperature indicator will be illuminated and a single chime tone is sounded. The indicator remains illuminated until a message from the PCM indicating that the engine coolant temperature is below the high end of normal is received, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the engine temperature indicator is cycled off and then on again by the appropriate engine temperature messages from the PCM.

The PCM continually monitors the engine coolant temperature sensor to determine the engine operating temperature. The PCM then sends the proper engine coolant temperature messages to the IC. If the IC turns on the engine temperature indicator due to a high engine temperature gauge reading, it may indicate that the engine or the engine cooling system requires service.

ESC INDICATOR

The Electronic Stability Control (ESC) indicator gives an indication to the vehicle operator when the ESC has been activated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the CAB and the Final Drive Control Module (FDCM) over the CAN data bus. The IC will illuminate the ESC/BAS indicator for about four seconds as a bulb test each time the ignition switch status transitions to ON.

The ESC indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the ESC/BAS indicator for the following reasons:

- **ESC Indicator Lamp-On Message** - Each time the IC receives an electronic **ESC/ indicator lamp-ON** message from the CAB indicating that the ESC system has been activated, the ESC indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **ESC Off Textual Message** - Each time the IC receives an electronic **ESC OFF indicator lamp-ON** message from the CAB indicating that the ESC system has been manually disabled, an **ESC OFF** textual message will appear within the IC electronic display unit. The **ESC OFF** textual message remains displayed until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **ESC Textual Warning Message** - When the CAB or FDCM detects certain monitored fault conditions, it will send electronic messages requesting the IC display a textual warning message. Each time the IC receives an electronic **ESC textual warning request** message from the CAB or FDCM, a **WARNING! LIMIT SPEED** textual message will appear within the IC electronic display unit to accompany an ESC indicator that is illuminated solid. This message indicates that the CAB or FDCM has detected a problem in one of the ESC system circuits or components.

The CAB and FDCM continually monitor the ESC circuits and sensors to decide whether the system is in good operating condition. The CAB or FDCM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the ESC/BAS system, the CAB, the FDCM, the IC, the CAN data bus or the electronic communication related to the ESC/BAS indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

FRONT FOG LAMP INDICATOR

The front fog lamp indicator gives an indication to the vehicle operator whenever the front fog lamps are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the BCM over the CAN data bus.

The front fog lamp indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path

to ground by the IC transistor. The IC will turn ON the front fog lamp indicator for the following reasons:

- **Front Fog Indicator Lamp-On Message** - Each time the IC receives an electronic **front fog indicator lamp-ON** message from the BCM indicating the front fog lamps are turned ON, the front fog lamp indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors a hard wired input from the exterior lighting switch to determine the appropriate outputs to the front fog lamps. The BCM activates or deactivates the front fog lamps then sends the proper lamp-ON or lamp-OFF message to the IC to control the front fog lamp indicator.

For proper diagnosis of the front fog lamp system, the BCM, the IC, the CAN data bus or the electronic communication related to front fog lamp indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

GAS CAP INDICATOR

The gas cap indicator gives an indication to the vehicle operator when there is a gross leak detected in the on-board fuel vapor recovery system. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The gas cap indicator function of the IC electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the gas cap indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the gas cap indicator for the following reasons:

- **Gas Cap Indicator Lamp-On Message** - Each time the IC receives an electronic **gas cap indicator lamp-ON** message from the PCM indicating there is a gross leak in the vapor recovery system, the gas cap indicator will be displayed. The indicator remains displayed until the IC receives a lamp-OFF message from the PCM, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first.

NOTE: If the On-Board Diagnostic (OBD) system in the vehicle determines that the fuel filler cap is loose, improperly installed or damaged, a gas cap ICON will be displayed in the electronic display unit. In this instance, verify that the gas cap is properly installed and tightened before proceeding with any further diagnosis.

The PCM continually monitors the on board vapor recovery system to determine whether there are air leaks in the system. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the gas cap indicator due to a monitored gross leak in the vapor recovery system, it may indicate that the gas cap has been removed or is improperly installed.

For proper diagnosis of the on board vapor recovery system, the PCM, the IC, the CAN data bus or the electronic communication related to gas cap indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

HIGH BEAM INDICATOR

The high beam indicator gives an indication to the vehicle operator whenever the headlamp high beams are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received from the BCM over the CAN data bus.

The high beam indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the high beam indicator for the following reasons:

- **High Beam Indicator Lamp-On Message** - Each time the IC receives an electronic **high beam indicator lamp-ON** message from the BCM or the Automatic High Beam Module (AHBM) (also known as SmartBeam® on vehicles so equipped) the high beam indicator will be illuminated. The high beam indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors electronic messages from the Steering Angle Sensor (SAS) based upon the status of the beam select switch and the AHBM to determine the proper headlamp beam control. The BCM activates or deactivates the headlamp high beams then sends the proper lamp-ON or lamp-OFF message back to the IC.

For proper diagnosis of the SAS, the AHBM, the BCM, the IC, the CAN data bus or the electronic communication related to high beam indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW COOLANT INDICATOR

The low coolant indicator gives an indication to the vehicle operator when the diesel engine coolant level is low. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The low coolant indicator function of the IC electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the low coolant indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the low coolant indicator for the following reasons:

- **Low Coolant Indicator Lamp-On Message** - Each time the IC receives an electronic **low coolant indicator lamp-ON** message from the PCM indicating the engine coolant level is low, the low coolant textual warning and icon are illuminated and a single chime tone is sounded. The low coolant textual warning and icon remain illuminated until the IC receives a lamp-OFF message from the PCM, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the textual warning and icon are cycled OFF and then ON again by the appropriate messages from the PCM.

The PCM continually monitors the engine coolant level switch on the coolant bottle to determine the level of the engine coolant. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the coolant low indicator and icon due to a low coolant level, it may indicate that the engine or the engine cooling system requires service.

For proper diagnosis of the engine coolant level switch, the PCM, the IC, the CAN data bus or the electronic communication related to low coolant indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW FUEL INDICATOR

The low fuel indicator gives an indication to the vehicle operator when the level of fuel in the fuel tank becomes low. This indicator is controlled by a transistor on the IC circuit board based upon programming and a hard wired input received by the IC from the fuel level sending unit on the fuel pump module in the fuel tank. The IC will illuminate the low fuel indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The low fuel indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the low fuel indicator for the following reasons:

- **Less Than 11 Percent Tank Full Input** - The BCM provides a constant current source to the fuel level sending unit, and monitors a return input on a fuel level sense circuit. The resistance through the fuel level sending unit increases as the fuel level falls, and decreases as the fuel level rises causing changes in the sense input voltage. Each time the fuel level sense input to the BCM indicates the fuel tank is about 11 percent full or less for 10 consecutive seconds and the vehicle speed is zero, or for 60 consecutive seconds and the vehicle speed is greater than zero, the BCM sends an electronic message to the IC. Then the IC moves the gauge needle to the appropriate position on the gauge scale; the low fuel indicator is illuminated and a single chime tone is sounded. The low fuel indicator remains illuminated until the fuel level sense input indicates that the fuel tank is greater than about 14 percent full for 10 consecutive seconds and the vehicle speed is zero, or for 60 consecutive seconds and the vehicle speed is greater than zero, or until the ignition switch transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the low fuel indicator is cycled OFF and then ON again by the appropriate inputs from the fuel level sending unit.
- **Less Than Empty Stop Input** - Each time the IC receives a fuel level message from the BCM that indicates the fuel level in the fuel tank is less than the **E** (or Empty) gauge needle stop position for five consecutive seconds, the gauge needle is moved to the low end of the gauge scale and the low fuel indicator is illuminated immediately. This input would indicate that the fuel level sense input to the BCM is a short circuit.
- **More Than Full Stop Input** - Each time the IC receives a fuel level message from the BCM that indicates the fuel level in the fuel tank is more than the **F** (or Full) gauge needle stop position for five consecutive seconds, the gauge needle is moved to the low end of the gauge scale and the low fuel indicator is illuminated immediately. This input would indicate that the fuel level sense input to the BCM is an open circuit.

The BCM continually monitors the fuel tank sending unit to determine the level of fuel in the fuel tank. The BCM then sends the proper electronic **fuel level** message to IC and other electronic modules in the vehicle over the CAN data bus. The BCM will store a DTC for any fault detected in the fuel level sense circuit.

For proper diagnosis of the fuel tank sending unit, the BCM, the IC, and the CAN data bus or the electronic communication related to low fuel indicator operation or fuel level data processing, a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW OIL PRESSURE INDICATOR

The low oil pressure indicator gives an indication to the vehicle operator when the engine oil pressure reading reflects a condition requiring immediate attention. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus.

The low oil pressure indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the low oil pressure indicator for the following reasons:

- **Engine Oil Pressure Low Message** - Each time the IC receives an electronic **engine oil pressure** message from the PCM indicating the pressure is about 6.9 kPa (1 psi) or lower, the low oil pressure indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the PCM message. The indicator remains illuminated solid or flashing until the IC receives a message from the PCM indicating that the pressure is above about 6.9 kPa (1 psi), or until the ignition switch status transitions to OFF, whichever occurs first. The IC will only turn the indicator ON in response to low engine oil pressure if the engine speed is greater than zero.

The PCM continually monitors the engine oil pressure sensor to determine the engine oil pressure. The PCM then sends the proper messages to the IC. If the IC turns ON the indicator after the bulb test, it may indicate that the engine or the engine oiling system requires service.

For proper diagnosis of the engine oil pressure sensor, the PCM, the IC, the CAN data bus or the electronic communication related to low oil pressure indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW TIRE PRESSURE INDICATOR

The Tire Pressure Monitor (TPM) indicator gives an indication to the vehicle operator of the status of the TPM system. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the Tire Pressure Module (TPM) (also known as the CORAX module) over the CAN data bus. The IC will illuminate the TPM indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The TPM indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the TPM indicator for the following reasons:

- **TPM Indicator Lamp-On Message** - Each time the IC receives an electronic **TPM indicator lamp-ON** message from the TPM, the TPM indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the TPM message. The indicator remains illuminated until the IC receives a lamp-OFF message from the TPM, or until the ignition switch status transitions to OFF position, whichever occurs first.
- **TPM Textual Warning Message** - When the TPM detects certain monitored fault conditions, it will send electronic messages requesting the IC display a textual warning message. Each time the IC receives an electronic **textual warning request** message from the TPM, a **SERVICE TIRE PRESS. SYSTEM** textual message will appear within the electronic display unit to accompany a flashing TPM indicator or to replace the TPM **TIRE LOW PRESSURE** textual message. This message indicates that the TPM has detected a problem in one of the TPM system components.
- **TPM Low Pressure Message** - On vehicles equipped with the optional premium version of the TPM system, each time the IC receives an electronic **low pressure** message from the TPM, a **LEFT FRONT**, **RIGHT FRONT**, **LEFT REAR** or **RIGHT REAR LOW PRESSURE** textual message will appear within the IC electronic display unit to accompany a solid TPM indicator. If the vehicle is equipped with a full-sized matching spare tire and wheel assembly, an electronic **spare low pressure** message from the TPM to the IC will cause a **SPARE LOW PRESSURE** textual message to appear in the electronic display unit, but the TPM indicator

will not illuminate. This message indicates that the TPM has received a low tire pressure input from the tire pressure sensor in the identified location on the vehicle. The premium TPM system is not offered in markets where rear fog lamps are an available option.

- **Communication Error** - If the IC receives no TPM lamp-ON or lamp-OFF messages from the TPM for six consecutive seconds, the TPM indicator is illuminated by the IC. The indicator remains controlled and illuminated by the IC until a valid lamp-ON or lamp-OFF message is received from the TPM.

The TPM performs a self-test each time the ignition switch status transitions to ON to decide whether the TPM system is in good operating condition and whether the tire inflation pressures are too high or too low. The TPM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the TPM indicator after the bulb test, it indicates that the inflation pressure of a tire is too low or that a malfunction has occurred and the TPM system is ineffective.

For proper diagnosis of the TPM system, the TPM, the IC, the CAN data bus or the electronic communication related to TPM indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

MALFUNCTION INDICATOR LAMP

The Malfunction Indicator Lamp (MIL) gives an indication to the vehicle operator when the PCM has recorded a DTC for an On-Board Diagnostics II (OBDII) emissions-related circuit or component malfunction. The MIL is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus. The IC will illuminate the MIL indicator for about fifteen seconds as a bulb test each time the ignition switch status transitions to ON.

The MIL LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the MIL for the following reasons:

- **MIL Lamp-On Message** - Each time the IC receives an electronic **MIL lamp-ON** message from the PCM, the indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the PCM message. For some DTCs, if a problem does not recur, the PCM will send a lamp-OFF message automatically. Other DTCs may require that a fault be repaired and the PCM be reset before a lamp-OFF message will be sent. For more information on the PCM, and the DTC set and reset parameters, (Refer to 25 - Emissions Control - Operation) .
- **Communication Error** - If the IC receives no lamp-ON or lamp-OFF messages from the PCM for 10 consecutive message cycles, the MIL is illuminated by the IC to indicate a loss of bus communication. The indicator remains controlled and illuminated by the IC until a valid message is received from the PCM.

The PCM continually monitors the fuel and emissions system circuits and sensors to decide whether the system is in good operating condition. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the MIL after the bulb test, it may indicate that a malfunction has occurred and that the fuel and emissions systems require service.

For proper diagnosis of the fuel and emissions systems, the PCM, the IC, the CAN data bus or the electronic communication related to MIL operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

NO BUS INDICATOR

The no bus indicator gives an indication to the vehicle operator when the IC detects a loss of electronic communication over the CAN data bus. This indicator is controlled by the IC logic circuit based upon programming and electronic messages not being received over the CAN data bus from the BCM.

The no bus indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the no bus indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the no bus indicator for the following reasons:

- **No Electronic Communication Messages** - Each time the ignition switch is turned to the ON position and the IC does not receive electronic communication messages over the CAN data bus, the no bus indicator is illuminated. The indicator remains illuminated until CAN bus communication is restored or until the ignition switch status transitions to OFF, whichever occurs first.

The IC continually monitors the CAN data bus to determine the status of many sensors and systems throughout the vehicle. If the IC detects the loss of CAN bus communication it illuminates the no bus indicator to alert the vehicle operator that it cannot provide accurate displays and outputs.

For proper diagnosis of the IC, the CAN data bus or the electronic communication related to no bus indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

POSITION LAMP INDICATOR

The position lamp indicator gives an indication to the vehicle operator whenever the position lamps are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the BCM over the CAN data bus.

The position lamp indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the position lamp indicator for the following reasons:

- **Position Lamp Indicator Lamp-On Message** - Each time the IC receives an electronic **position lamp indicator lamp-ON** message from the BCM indicating the position lamps are turned ON, the position lamp indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors a hard wired input from the exterior lighting switch to determine the appropriate outputs to the park lamps. The BCM activates or deactivates the park lamps then sends the proper lamp-ON or lamp-OFF message to the IC to control the position lamp indicator.

For proper diagnosis of the position lamp system, the BCM, the IC, the CAN data bus or the electronic communication related to position lamp indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

POWER LIFTGATE INDICATOR

The power liftgate indicator gives an indication to the vehicle operator of the power liftgate system status or when the system has been automatically disabled. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the Power LiftGate Module (PLGM).

The power liftgate indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the power liftgate indications can be displayed regardless of the ignition switch status. The IC will turn ON the power liftgate indicator for the following reasons:

- **Unlock To Operate Message** - Each time the IC receives an electronic **unlock to operate** message from the PLGM, the **UNLOCK TO OPERATE** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Put In Park To Operate Message** - Each time the IC receives an electronic **put in PARK to operate** message from the PLGM, the **PUT IN PARK TO OPERATE** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Function Disabled Message** - Each time the IC receives an electronic **function disabled** message from the PLGM, the **FUNCTION DISABLED** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Obstacle Detected Message** - Each time the IC receives an electronic **obstacle detected** message from the PLGM, the **OBSTACLE DETECTED** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Manually Close To Operate Message** - Each time the IC receives an electronic **manually close to operate** message from the PLGM, the **MANUAL CLOSE TO OPERATE** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.

The PLGM continually monitors the power liftgate circuits and sensors to determine the proper outputs to the power liftgate components. The PLGM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the power liftgate, the PLGM, the IC, the CAN data bus or the electronic communication related to power liftgate indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

REAR FOG LAMP INDICATOR

The rear fog lamp indicator gives an indication to the vehicle operator whenever the rear fog lamps are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the BCM over the CAN data bus.

The rear fog lamp indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the rear fog lamp indicator for the following reasons:

- **Rear Fog Indicator Lamp-On Message** - Each time the IC receives an electronic **rear fog indicator lamp-ON** message from the BCM indicating that the rear fog lamps are turned ON, the rear fog lamp indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors a hard wired input from the exterior lighting switch to determine the appropriate outputs to the rear fog lamps. The BCM activates or deactivates the rear fog lamps then sends the proper lamp-ON or lamp-OFF message to the IC to control the rear fog lamp indicator.

For proper diagnosis of the rear fog lamp system, the BCM, the IC, the CAN data bus or the electronic communication related to rear fog lamp indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

REMOTE START INDICATOR

The remote start indicator gives an indication to the vehicle operator of the remote start system status. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the BCM and the Radio Frequency Hub (RF Hub).

The remote start indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the remote start indications can be illuminated regardless of the ignition switch status. The IC will turn ON the remote start indicator for the following reasons:

- **Remote Start Active Messages** - Each time the IC receives an electronic**remote start active** message from the BCM, the **REMOTE START ACTIVE - PUSH START BUTTON** textual message is displayed. The message is displayed while the current remote start event remains active (about 15 minutes), until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to ON, whichever occurs first.
- **Remote Start Abort Messages** - Each time the IC receives a combination of electronic **remote start abort** and **door ajar**, **hood ajar**, **liftgate ajar** or **low fuel** messages from the BCM the **REMOTE START ABORTED** and appropriate **DOOR AJAR**, **HOOD AJAR**, **LIFTGATE AJAR** or **FUEL LOW**textual messages are displayed. The messages are displayed while the current remote start event remains active (about 15 minutes), until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to ON, whichever occurs first.
- **Remote Start Disabled Messages** - Each time the IC receives an electronic **remote start disabled** message from the BCM the **REMOTE START DISABLED - START VEHICLE TO RESET** textual message is displayed. The message is displayed while the current remote start event remains active (about 15 minutes), until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to START, whichever occurs first.

The BCM continually monitors the remote start system inputs and the RF Hub to determine the proper outputs to the remote start components. The BCM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the remote start system, the RF hub, the BCM, the IC, the CAN data bus or the electronic communication related to remote start indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

SEAT BELT INDICATOR

The seat belt indicator gives an indication to the vehicle operator of the status of the driver side front seat belt (export market vehicles) or driver and passenger front seat

belts (domestic market vehicles). This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received over the CAN data bus from the ORC.

The seat belt indicator also includes a programmable enhanced seat belt reminder or BELTMINDER feature that is enabled when the vehicle is shipped from the factory. This BELTMINDER feature can be disabled and enabled by the customer using a specific programming event sequence, or by the dealer using a diagnostic scan tool.

The seat belt indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the seat belt indicator for the following reasons:

- **Seat Belt Reminder Function** - Each time the IC receives a battery current input on the fused ignition switch (run-start) circuit, the indicator will be illuminated as a seat belt reminder for about six seconds, or until the ignition switch status transitions to OFF, whichever occurs first. This reminder function will occur regardless of the status of the seat belt switch input to the ORC.
- **Front Seat Belt Not Buckled - Beltminder Active** - Following the seat belt reminder function, each time the IC receives an electronic **seat belt indicator lamp-On** message from the ORC while the ignition switch status is START or ON, the indicator will be illuminated. In addition, if the front seat belt remains unbuckled about 18 to 25 seconds after the conclusion of the seat belt reminder function with the vehicle speed greater than about 8 kilometers-per-hour (5 miles-per-hour), the seat belt indicator will begin to cycle between flashing ON and OFF for 3 seconds, then lighting solid for 2 seconds. The seat belt indicator will continue to cycle between flashing and solid illumination for 13 complete cycles, until the seat belt switch sense inputs to the ORC are closed circuits (seat belt switch closed = seat belt buckled), or until the ignition switch status transitions to OFF, whichever occurs first.
- **Front Seat Belt Not Buckled - Beltminder Inactive** - Following the seat belt reminder function, each time the IC receives an electronic **seat belt indicator lamp-On** message from the ORC while the ignition switch status is START or ON, the indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the ORC or until the ignition switch status transitions to OFF, whichever occurs first.

Each seat belt switch is connected in series between source current and a sense circuit from the ORC. The ORC continually monitors the seat belt switch circuits then sends the proper lamp-on or lamp-off messages to the IC. The seat belt switch inputs to the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. For proper diagnosis of the ORC, the IC, the CAN data bus or the electronic communication related to seat belt indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

SECURITY INDICATOR

The security indicator gives an indication to the vehicle operator when the Vehicle Theft Security System (VTSS) is arming or is armed. On vehicles equipped with the Sentry Key Immobilizer System (SKIS), the security indicator also gives an indication to the vehicle operator of the status of the SKIS. This indicator is controlled by a transistor on the IC circuit board based upon a hard wired input to the IC from the BCM and electronic messages received by the BCM from the RF hub over the CAN data bus. The BCM will illuminate the security indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The security indicator LED is completely controlled by the BCM logic circuit, and that logic will allow this indicator to operate whenever the BCM receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the BCM. Depending upon the programmed condition the indicator can be illuminated solid, flashed at a slow rate (0.5 Hertz, 12.5 percent duty cycle), or flashed at a fast rate (1 Hertz, 50 percent duty cycle). The IC will turn ON the security indicator for the following reasons:

- **VTSS Indication** - During the 16 second VTSS arming function, the BCM will flash the security indicator ON and OFF repeatedly at a steady, fast rate to indicate that the VTSS is in the process of arming. Following successful VTSS arming, the BCM flashes the security indicator ON and OFF continuously at a slower rate to indicate that the VTSS is armed. The security indicator continues flashing at the slower rate until the VTSS is disarmed or triggered. If the VTSS has alarmed and rearmed, the BCM will flash the security indicator at a steady, slow rate for about 30 seconds after the VTSS is disarmed.
- **SKIS Indicator Lamp-On Message** - Each time the BCM receives an electronic **SKIS indicator lamp-ON** message from the RF hub, the security indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the RF hub message. The indicator remains illuminated solid or continues to flash until the BCM receives a lamp-OFF message from the RF hub, or until the ignition switch status transitions to OFF, whichever occurs first. For more information on the SKIS and the security indicator control parameters, (Refer to 08 - Electrical/8Q - Vehicle Theft Security - Operation) .
- **SKIS Textual Message** - When the RF hub detects certain monitored conditions or is placed in the programming mode it will send electronic messages requesting the IC display textual messages, and the appropriate textual message or combination of messages is illuminated in the electronic display unit. **PROGRAMMING ACTIVE**, **NEW KEY PROGRAMMED**, **REMOTE KEY BATTERY LOW** and **SERVICE SECURITY KEY** messages appear individually, while a **KEY NOT PROGRAMMED** message is followed by either a **DAMAGED KEY**, **INVALID KEY** or **EXCEEDED KEY PROGRAM LIMIT** message and an **INVALID KEY** message is followed by a **TRY ALTERNATE KEY** message. The textual messages related to key programming are active only on vehicles sold in markets where customer programming is an available feature of the SKIS.
- **Communication Error** - If the BCM receives no lamp-ON or lamp-OFF messages from the RF hub for 10 consecutive message cycles, the security indicator is illuminated by the BCM. The indicator remains controlled and illuminated by the BCM until a valid lamp-ON or lamp-OFF message is received from the RF hub.

The BCM circuitry controls the security indicator whenever the ignition switch status is OFF and the VTSS is arming, armed, or alarming. Whenever the ignition switch status is ON or START, RF hub performs a self-test to decide whether the SKIS is in good operating condition and whether a valid key is present within the vehicle. The RF hub then sends the proper lamp-ON or lamp-OFF message to the BCM. If the BCM flashes the security indicator when the ignition switch transitions to ON, or turns ON the security indicator solid after the bulb test, it indicates that a SKIS malfunction has occurred or that the SKIS is ineffective.

For proper diagnosis of the VTSS, the SKIS, the BCM, the RF hub, the IC, the CAN data bus or the electronic communication related to security indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

SERVICE COLUMN LOCK INDICATOR

The service column lock indicator gives an indication to the vehicle operator when the RF hub has recorded a DTC for a steering column shaft lock module circuit or component malfunction. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received by the IC from the RF hub over the CAN data bus.

The service column lock indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the service column lock indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the service column lock indicator for the following reasons:

- **Service Column Lock Indicator Lamp-On Message** - Each time the IC receives an electronic **service column lock indicator lamp-ON** message from the RF hub, the service column lock indicator will be illuminated. The indicator remains illuminated for about five seconds, until the IC receives a lamp-OFF message from the RF hub, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first.

The RF hub continually monitors the steering column shaft lock module circuits and components to determine the condition of the system. The RF hub then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the shaft lock module, the RF hub, the IC, the CAN data bus or the electronic communication related to service column lock indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

TRACTION CONTROL INDICATOR

The traction control indicator gives an indication to the vehicle operator when the ESC/BAS/Traction Control System (TCS) has been activated. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received by the IC from the CAB over the CAN data bus. The IC will illuminate the traction control indicator for about four seconds as a bulb test each time the ignition switch status transitions to ON.

The traction control indicator is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the indicator will always be OFF when the ignition switch status is anything except ON or START. The indicator only illuminates when it is provided a path to ground by the IC circuitry. The IC will turn ON the traction control indicator for the following reasons:

- **Traction Control Indicator Lamp-On Message** - Each time the IC receives an electronic **traction control indicator lamp-ON** message from the CAB indicating that the ESC/BAS/TCS has been activated, the traction control indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the CAB message. The indicator remains illuminated solid or continues to flash until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.

The CAB continually monitors the traction control switch to determine the proper outputs to the components of the Antilock Brake System (ABS). The CAB then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the traction control switch, the ESC/BAS/TCS, the CAB, the IC, the CAN data bus or the electronic communication related to traction control indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

TRANSMISSION TEMPERATURE INDICATOR

The transmission over-temperature indicator gives an indication to the vehicle operator when the transmission fluid temperature is excessive, which may lead to accelerated transmission component wear or failure. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the TCM.

The transmission over-temperature indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the transmission over-temperature indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the transmission over-temperature indicator for the following reasons:

- **Trans Over-Temp Indicator Lamp-On Message** - Each time the IC receives an electronic **trans over-temp indicator lamp-ON** message from the TCM indicating that the fluid temperature is too high, the transmission over-temperature indicator will be illuminated and a single chime tone is sounded. The indicator remains illuminated for about five seconds, until the IC receives a lamp-OFF message from the TCM, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the indicator is cycled OFF and then ON again by the appropriate lamp-ON and lamp-OFF messages from the TCM.

The TCM continually monitors the transmission temperature sensor to determine the transmission operating condition. The TCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC illuminates the transmission over-temperature indicator due to a high transmission oil temperature condition, it may indicate that the transmission or the transmission cooling system are being overloaded or that they require service.

For proper diagnosis of the transmission temperature sensor, the TCM, the IC, the CAN data bus or the electronic communication related to transmission over-temperature indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

TURN SIGNAL INDICATORS

The turn signal indicators give an indication to the vehicle operator that the turn signal (left or right indicator flashing) or hazard warning (both left and right indicators flashing) have been selected and are operating. These indicators are controlled by transistors on the IC cluster electronic circuit board based upon cluster programming and electronic messages received from the BCM over the CAN data bus.

Each turn signal indicator Light Emitting Diode (LED) unit is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, each LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the turn signal indicators for the following reasons:

- **Turn Signal Indicator Lamp-On Message** - Each time the IC receives an electronic **right** or **left turn signal indicator lamp-On** message from the BCM over the CAN data bus, the appropriate turn signal indicator will be flashed on and off. The BCM messages to the IC also control the flash rate of the turn signal indicators, as well as the click rate of an electromechanical relay soldered onto the IC electronic circuit board that emulates the sound emitted by a conventional turn signal flasher. The turn signal indicators continue to flash on and off until the IC receives a lamp-OFF message from the BCM, or until the ignition switch status transitions to OFF, whichever occurs first.
- **Hazard Warning Indicator Lamp-On Message** - Each time the IC receives an electronic **hazard warning indicator lamp-On** message from the BCM over the CAN data bus, both turn signal indicators will be flashed on and off. The BCM messages to the IC also control the flash rate of the turn signal indicators, as well as the click rate of an electromechanical relay soldered onto the IC electronic circuit board that emulates the sound emitted by a conventional hazard warning flasher. The turn signal indicators continue to flash on and off until the IC receives a lamp-OFF message from the BCM.
- **Turn Signal-On Textual Warning Message** - When the BCM detects that a turn signal has been active continuously for 1.6 kilometers (1 mile) with the vehicle speed greater than 22 kilometers-per-hour (15 miles-per hour) a **TURN SIGNAL ON** textual message and flashing right or left turn signal icon will appear within the IC electronic display unit and a chime tone will be sounded.
- **Lamp Out Mode** - If the BCM detects an ineffective turn signal lamp or circuit, it increases the flash rate for the remaining operative turn signals and sends an electronic message to the IC. The IC then increases the flash rate of the turn signal indicators and the click rate of the electromechanical relay to provide an indication of the problem to the vehicle operator.

The IC continually monitors electronic messages from the BCM to determine the proper turn signal and hazard warning indicator operation.

For proper diagnosis of the turn signal and hazard warning system, the multi-function switch, the BCM, the IC, the CAN data bus or the electronic communication related

to turn signal indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

WAIT-TO-START INDICATOR

The wait-to-start indicator gives an indication to the vehicle operator when the diesel engine is too cool for efficient and reliable engine starting, and the engine glow plugs are energized in their preheat operating mode. This indicator is controlled by a transistor on the IC electronic circuit board based upon programming and electronic messages received by the IC from the ECM over the CAN data bus.

The wait-to-start indicator is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the indicator will always be OFF when the ignition switch status is anything except ON or START. The icon only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the wait-to-start indicator for the following reasons:

- **Wait-To-Start Indicator Lamp-On Message** - Each time the IC receives an electronic **wait-to-start indicator lamp-ON** message from the ECM indicating that the air temperature is too cool for efficient and reliable engine starting and the glow plugs are energized in their preheat mode, the wait-to-start indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the ECM, until the ECM detects that the engine is running, or until the ignition switch status transitions to OFF, whichever occurs first.

The ECM continually monitors the glow plug control circuits to determine when they are energized in their preheat operating mode. The ECM then sends the proper lamp-ON or lamp-OFF message to the IC. For proper diagnosis of the wait-to-start indicator, the ECM, the IC, the CAN data bus or the electronic communication related to wait-to-start indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

WASHER FLUID INDICATOR

The washer fluid indicator gives an indication to the vehicle operator that the fluid level in the washer reservoir is low. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received from the BCM over the CAN data bus.

The washer fluid indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the washer fluid indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the washer fluid indicator for the following reasons:

- **Washer Fluid Indicator Lamp-On Message** - Each time the IC receives an electronic **washer fluid indicator lamp-ON** message from the BCM indicating that a low washer fluid condition has been detected for 60 consecutive seconds, the washer fluid indicator is illuminated and a single chime tone is sounded. The indicator remains illuminated until the IC receives lamp-OFF messages for 60 consecutive seconds from the BCM, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the washer fluid indicator is cycled OFF and then ON again by the appropriate lamp-ON and lamp-OFF messages from the BCM.

The BCM continually monitors the washer fluid level switch in the washer reservoir to determine the level of the washer fluid. The BCM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the washer fluid level switch, the BCM, the IC, the CAN data bus or the electronic communication related to washer fluid indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

WATER-IN-FUEL INDICATOR

The water-in-fuel indicator gives an indication to the vehicle operator when there is excessive water in the fuel system. This indicator is controlled by the IC based upon programming and electronic messages received from the ECM over the Controller Area Network (CAN) data bus.

The water-in-fuel indicator is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the indicator will always be OFF when the ignition switch status is anything except ON or START. The icon only illuminates when it is provided a path to ground by the IC transistor. Each time the ignition switch status transitions to ON the water-in-fuel indicator is illuminated for about two seconds as a bulb test. The water-in-fuel indicator will be turned ON for the following reasons:

- **Water-In-Fuel Indicator Lamp-On Message** - Each time the IC receives an electronic **water-in-fuel lamp-ON** message from the ECM indicating that there is excessive water in the diesel fuel system, the water-in-fuel indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the ECM, or until the ignition switch status transitions to OFF, whichever occurs first.

The ECM continually monitors the water-in-fuel sensor to determine whether there is excessive water in the diesel fuel system. The ECM then sends the proper lamp-ON or lamp-OFF message to the IC. For proper diagnosis of the water-in-fuel operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

OPERATION

The microprocessor-based Instrument Cluster (IC) hardware and software uses various inputs to control the gauges and indicators visible on the face of the IC. The Vehicle Theft Alarm (VTA) lamp input is hard wired, the remaining inputs are in the form of electronic messages that are transmitted by other electronic modules over the Controller Area Network (CAN) data bus. (Refer to 08 - Electrical/8E - Electronic Control Modules/COMMUNICATION - Operation) .

The IC may also produce audible warnings for other electronic modules in the vehicle based upon electronic **tone request** messages received over the CAN data bus. Each audible warning is intended to provide the vehicle operator with an audible alert to supplement a visual indication.

The IC circuitry operates on battery current received through a non-switched fused B(+) circuit and on battery current received through a fused ignition output (run-start) circuit. This arrangement allows the IC to provide some features regardless of the ignition switch status, while other features will operate only when the status of the ignition switch is ON or START. The circuitry is grounded through a ground circuit of the instrument panel wire harness.

The IC also has a self-diagnostic test capability that tests each of the CAN bus message-controlled functions of the IC. This test illuminates the appropriate indicators, positions the gauge needles at several predetermined calibration points across the gauge faces and illuminates all segments of the EVIC TFT display. The EVIC will display the hardware/software version, and the CAN Vehicle Maintenance Monitor (VMM) used in the IC. (Refer to 08 - Electrical/8J - Instrument Cluster - Diagnosis and Testing) .

THIN FILM TRANSISTOR DISPLAY

The Thin Film Transistor (TFT) display unit is integrated into and soldered onto the IC electronic circuit board. With the status of the ignition switch OFF or ACCESSORY, the TFT display is activated when the driver door is opened (Rental Car mode) and deactivated when the driver door is closed. Otherwise, the display unit is active when the ignition switch status is ON or START, and inactive when the ignition switch status is OFF or ACCESSORY.

The IC TFT display unit has several display capabilities. The TFT unit displays odometer, trip odometer, gear selector indication (PRNDL) for models with an automatic transmission, several warning or reminder indications and various diagnostic information when certain fault conditions exist. The push buttons in the EVIC switch pod on the left horizontal spoke of the steering wheel are used to control some of the display modes of the TFT. (Refer to 08 - Electrical/8M - Message Systems/Message Center/CENTER, Electronic Vehicle Information - Operation) .

CLUSTER ILLUMINATION

Instrument Cluster (IC) general illumination lighting is supplied by several Light Emitting Diode (LED) units controlled by the IC, and are illuminated at full intensity anytime the ignition switch status is ON or RUN. The illumination intensity of these lamps can be adjusted only when the vehicle exterior lighting is turned ON by rotating the panel lamps dimmer thumbwheel of the dimmer module (down to dim, up to brighten). The IC monitors a CAN bus input from the Body Control Module (BCM) to determine illumination intensity.

REMOVAL

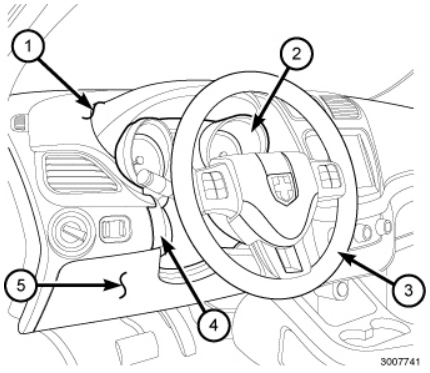
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **If replacing the cluster, take note of the mileage before disconnecting the battery, so the replacement cluster can be programmed with the correct mileage.**

CLUSTER ASSEMBLY

1. Disconnect and isolate the negative battery cable.
2. Remove the kneeblocker (Refer to 23 - Body/Instrument Panel/KNEEBLOCKER/Removal) .
3. Position the steering column assembly to its lowest position.
4. Using a trim tool, release the clips and position the steering column seal (4) back.
5. Remove the two lower fasteners that secure the instrument cluster (2) assembly to the instrument panel.
6. Pull the top of the instrument cluster back to release the to upper retaining clips.
7. Disconnect the instrument cluster wire harness connector from the back of the cluster housing.
8. Remove the instrument cluster from the vehicle.



CLUSTER MASK, HOOD AND LENS

1. Disconnect and isolate the negative battery cable.
2. Remove the instrument cluster from the instrument panel.
3. Remove the six screw (4) that secure the hood and mask to the cluster housing (1).
4. Working around the perimeter of the cluster housing, disengage the integrated latches (2) that secure the cluster mask to the cluster housing.

5. Remove the cluster mask from the face of the instrument cluster.

NOTE: The lens assemblies for this vehicle can be serviced separately from side to side.

6. To remove the lens and hood assemblies, disengage the integrated latches that secure the assembly to the cluster housing, and remove.

STANDARD PROCEDURE - ENHANCED SEATBELT REMINDER PROGRAMMING

The seatbelt indicator also includes a programmable enhanced seatbelt reminder or “BeltAlert®” feature that is enabled when the vehicle is shipped from the factory. This BeltAlert® feature provides extended, and modified visual seatbelt indicator, and audible chime warning responses to an unbuckled driver, or front passenger seat belt. For front passenger seats equipped with the BeltAlert® feature, the warning system may be triggered when an animal or heavy object is on the front passenger seat, or when the seat is folded flat (if equipped). The beltminder feature may be disabled or enabled by the customer using the programming sequence that follows, or by the dealer using a diagnostic scan tool. The following sequence of events must occur within sixty (60) seconds of the ignition switch being placed in the On position in order for the programming to be completed successfully.

1. With the ignition switch in any position except On or Start, buckle the driver side front seat belt.
2. Turn the ignition switch to the On position and wait for the seatbelt indicator reminder function to conclude (about six seconds).
3. Unbuckle and buckle the driver side front seat belt three or more times, ending with the belt buckled.
4. Turn the ignition switch to any position except On or Start to toggle the BeltAlert® feature from its current setting (from active to inactive, or from inactive to active). A single chime tone will provide an audible confirmation that the programming sequence has been successfully completed.

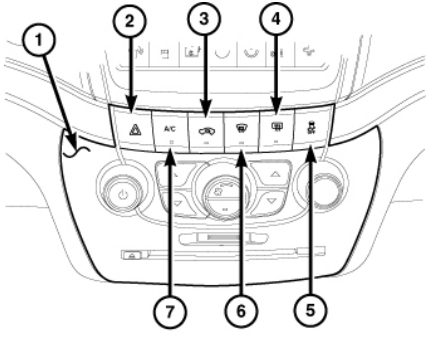
DESCRIPTION

The Accessory Switch Bank Module (ASBM) for this vehicle is located in the center stack area of the instrument panel. The accessory switch back, the a/c and heater controls, and the radio hard controls are a complete unit and only serviced as such. These switches vary from a single momentary push button switch, to momentary push button switches; depending on the equipment or systems they support. The unit includes the following switches:



- **Hazard Warning Switch (1)**
- **A/C On/Off switch (2)**
- **Windshield defroster On/Off switch (3)**
- **Rear Defroster On/Off switch (4)**
- **Electronic Stability Control Off (5)**

The switch housing and the push buttons are constructed of molded plastic. Each push button has a smooth finish and is clearly identified with the appropriate text and International Control and Display Symbol icons. Several of the push buttons feature Light Emitting Diode (LED) units to give the vehicle operator an indication when the function of that switch is currently active.

Panel lamps dimmer controlled illumination lamps integral to the circuit board within the switch provide back lighting for visibility at night, but these lamps are not serviceable. The individual switches in the switch bank cannot be repaired and are not serviced individually. If any component within the switch bank is ineffective or damaged, the complete assembly must be replaced.

OPERATION

The ambient temperature sensor is a variable resistor that operates on a five-volt reference signal. The resistance in the sensor changes as temperature changes, changing the temperature sensor signal circuit voltage to the Body Control Module (BCM) (also known as the Common Body Controller/CBC). Based upon the resistance in the sensor, the BCM sends electronic **outside ambient temperature** messages over the Controller Area Network (CAN) data bus for use by other electronic modules in the vehicle. The Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) Electronic Vehicle Information Center (EVIC) display receives and reads the electronic messages from the BCM, then displays the proper ambient temperature.

OPERATION

The Compass Display system uses both non-switched and ignition switched sources of battery current so that some of its features remain operational at any time, while others may only operate with the ignition switch in the ON position. When the ignition switch is turned to the ON position, the display will return to the last function being displayed before the ignition was turned to the OFF position.

The Compass Temperature Display system is comprised of several different components that communicate over the Controller Area Network (CAN) and Local Interface Network (LIN) Data Bus circuits. If the system is inoperative a scan tool and the appropriate diagnostic information must be used to diagnose the system and related data buses.

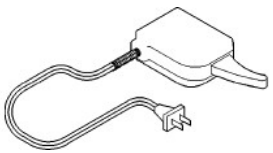
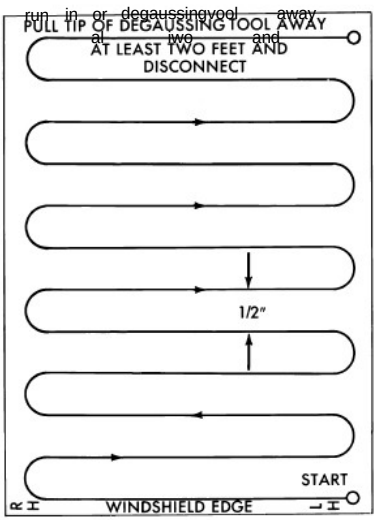
COMPASS DEMAGNETIZING

Special Tools: Click to display a list of tools used in this procedure

A degaussing tool (Special Tool 6029) is used to demagnetize, or degauss, the roof panel above the remote compass module. Equivalent units must be rated as continuous duty for 110/115 volts and 60 Hz. They must also have a field strength of over 350 gauss at 7 millimeters (0.25 inch) beyond the tip of the probe.



Demagnetize the roof panel as follows:



J908E-27

1. Be certain that the ignition switch is in the Off position, before you begin the demagnetizing procedure.
2. Place a piece of paper approximately 22 by 28 centimeters (8.5 by 11 inches), oriented on the vehicle lengthwise from front to rear, on the exterior surface of the roof panel at the left D-pillar in the area of the compass module. The purpose of the paper is to protect the roof panel from scratches, and to define the area to be demagnetized.
3. Connect the degaussing tool to an electrical outlet, while keeping the tool at least 61 centimeters (2 feet) away from the compass unit.
4. Slowly approach the center line of the roof panel at the windshield header, with the degaussing tool connected.
5. Contact the roof panel with the plastic coated tip of the degaussing tool. Be sure that the template is in place to avoid scratching the roof panel. Using a slow, back-and-forth sweeping motion, and allowing 13 millimeters (0.50 inch) between passes, move the tool at least 11 centimeters (4 inches) to each side of the roof center line, and 28 centimeters (11 inches) back from the windshield header.
6. With the degaussing tool still energized, slowly back it away from the roof panel. When the tip of the tool is at least 61 centimeters (2 feet) from the roof panel, disconnect the tool.
7. Calibrate the compass and adjust the compass variance. (Refer to 08 - Electrical/8M - Message Systems/Message Center/MODULE, Compass - Standard Procedure) .

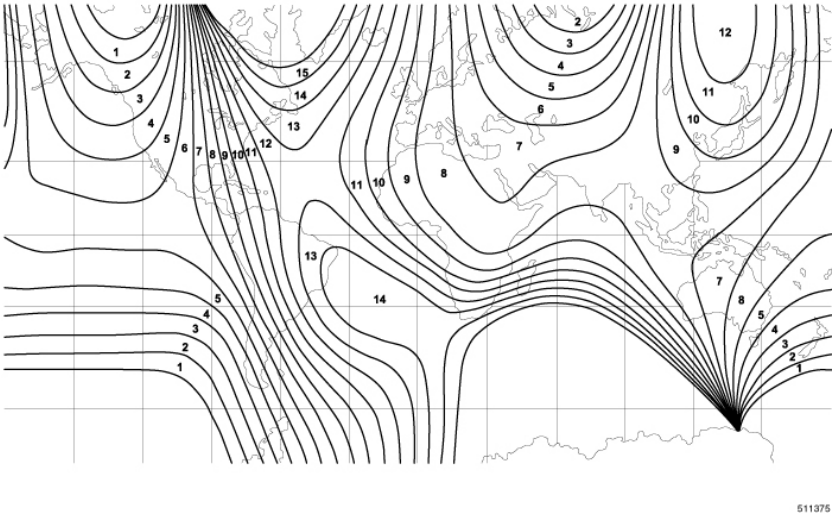
COMPASS VARIANCE ADJUSTMENT



Compass variance, also known as magnetic declination, is the difference in angle between magnetic north and true geographic north. In some geographic locations, the difference between magnetic and geographic north is great enough to cause the compass to give false readings. If this problem occurs, the compass variance must be set.

NOTE: If the vehicle is taken on long trips into a new variance zone the compass function may be effected. Compass variance will need to be updated to the new zone number to function properly.

NOTE: The default for the compass variance from the factory is 8.

Set the compass variance manually as follows:

1. Using the Variance Settings Map, find your geographic location and note the zone number.
2. Turn the ignition switch to the ON/RUN position.
3. Using the U-Connect Touch ™ screen, select **SETTINGS** either from the hard controls on the side of the screen, or from the menu selections at the bottom of the screen, depending on model.
4. Scroll through the menu, and select **COMPASS VARIANCE**.

5. Once selected, toggle through the zone numbers (1-15), until the zone number for your geographic location appears in the display. The zone number will set automatically.

NOTE: The default for the compass variance from the factory is 8. During programming, the Zone value will wrap around from Zone 15 to Zone 1.

6. Press the **BACK** button to return to the main menu.

7. Confirm that the correct direction is now indicated by the compass.

MANUAL COMPASS CALIBRATION

CAUTION: **Do not place any external magnets, such as magnetic roof mount antennas, in the vicinity of the Remote Compass Module (RCM) located under the left rear section of the roof panel. Do not place any electronic devices (cell phones, laptop computers, PDAs, portable DVD players, etc), on or near this section of the exterior roof panel as the RCM performance may be effected. Do not use magnetic tools when servicing the RCM.**

NOTE: Confirmation that the proper variance zone is programmed, is recommended whenever manual compass calibration is performed, (Refer to 08 - Electrical/8M - Message Systems/Message Center/MODULE, Compass - Standard Procedure) for the appropriate procedure.

The electronic compass unit features a self-calibrating design, which simplifies the calibration procedure. This feature automatically updates the compass calibration while the vehicle is being driven. This allows the compass unit to compensate for small changes in the residual magnetism that the vehicle may acquire during normal use. If the compass readings appear to be erratic or the Electronic Vehicle Information Center (EVIC) displays “CAL”, perform the following manual calibration procedure. Also, any time EVIC service replacement components are installed, they must be calibrated using this procedure. Do not attempt to calibrate the compass near large metal objects such as other vehicles, large buildings, or bridges; or, near overhead or underground power lines.

NOTE: Do not attempt to calibrate the compass near large metal objects such as other vehicles, large buildings, or bridges; or, near overhead or underground power lines.

NOTE: If the compass display indicates an inaccurate compass heading or the display is locked up, the RCM (if equipped) may be inoperative and require replacement.

NOTE: If the “CAL” message remains in the display, either there is excessive magnetism near the compass, or the EVIC is inoperative. Attempt the calibration procedure at least one more time before performing EVIC diagnosis.

NOTE: If the wrong direction is still indicated in the compass display, the area selected for calibration may be too close to a strong magnetic field. Repeat the manual calibration procedure in another location.

Calibrate the compass manually as follows:

1. Start the engine but leave the vehicle in “PARK” .
2. Using the U-Connect Touch ™ screen, select **SETTINGS** either from the hard controls on the sides of the screen, or from the menu selections at the bottom of the screen, depending on model.
3. Scroll through the menu, and select **CALIBRATE COMPASS**.
4. Select **ON** , the “CAL” symbol will come on solid in the EVIC display next to the compass direction that is displayed.

5. Slowly drive the vehicle on a level surface away from large metal objects, and power lines. Drive the vehicle through two or more**complete** circles, not exceeding 8 km/h (5 mph). The “CAL” message will disappear from the display to indicate successful compass calibration.

6. Confirm that the correct direction is now indicated by the compass.

7. Press the **BACK** button to return to the main menu.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

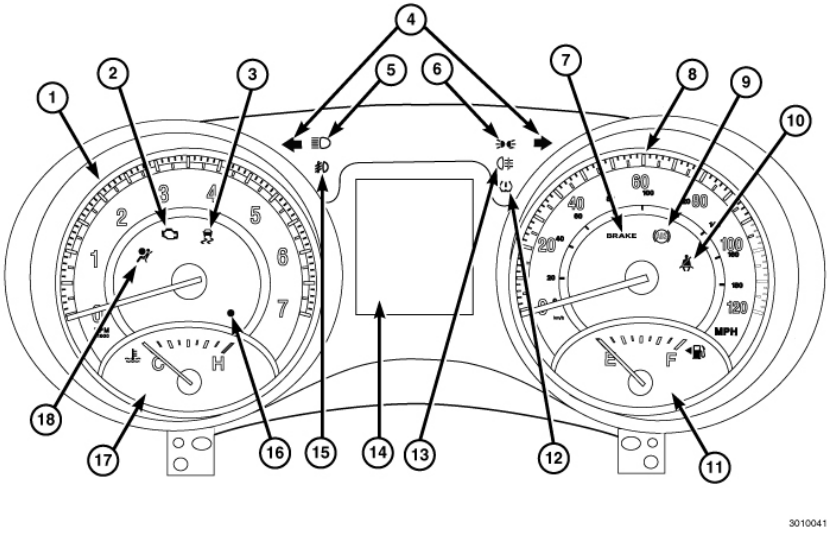
DESCRIPTION



The Electronic Vehicle Information Center (EVIC) features a driver-interactive display (14). The display is a Thin Film Transistor (TFT) type of Liquid Crystal Display (LCD), and is located directly in the center of the Instrument Cluster (IC) between the two gauge pods.

The EVIC displays many textual messages for vehicle systems support as well as your more common vehicle features, and options. These features and options include: Odometer (ODO), Trip A and Trip B odometer readouts, PRNDL, and compass heading, and ambient temperature readouts. The EVIC function buttons; located on the left spoke of the steering wheel can be used to scroll through the different features.

The EVIC system is comprised of several different components. Those components are:

- Instrument Cluster (IC)
- Ambient Temperature Sensor
- Remote Compass Module (RCM)
- Body Control Module (BCM)
- Controller Area Network (CAN) Data Bus
- Local Interface Network (LIN) Data Bus

The EVIC display is part of the Instrument Cluster assembly and is not serviced as a separate component. If the display is inoperative the complete Instrument Cluster assembly must be replaced, (Refer to 08 - Electrical/8J - Instrument Cluster - Removal) .

2014 Dodge JC - DODGE JOURNEY

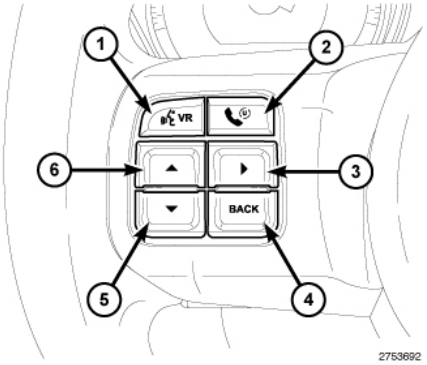
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Electronic Vehicle Information Center (EVIC) uses both fused B(+) and ignition switched sources of battery current so that some of its features remain operational at any time, while others may only operate with the ignition switch in the ON position. When the ignition switch is turned to the ON position, the EVIC display will return to the last function being displayed before the ignition was turned to the OFF position.

The EVIC system is comprised of several different components that communicate over the Controller Area Network (CAN) and Local Interface Network (LIN) data buses. **If the system is inoperative a scan tool and the appropriate diagnostic information must be used to diagnose the system.**

The EVIC function buttons are used to operate the different functions of the EVIC system. Pressing and releasing the **MENU** buttons (5 & 6) allows the driver to scroll though and select the Compass/Temperature, Trip Computer, Personal Settings or System Status functions. The **STEP** button (3) allows the selection of setting or resetting of the function currently displayed at that time. Pressing and releasing the **BACK** button (4) will cause the EVIC to return to the main menu.



EVIC DISPLAY MODES

SYSTEM STATUS MODE

Displays warnings and user interaction messages. Initial warnings will be displayed accompanied by a series of audible beeps. Critical text warnings will be displayed until the failure is corrected. Non-critical text warnings will be displayed for 60 seconds. The driver can scroll to view multiple messages by using the menu buttons.

When the appropriate conditions exist, the EVIC displays the following messages:

- **Cal** - if equipped with a compass module and without the optional navigation system.
- **Coolant Low** - accompanied by a single chime.
- **Exhaust Service Required - See Dealer Now** - Diesel models only.
- **Exhaust System - Regeneration Required Now** - Diesel models only.
- **Key In Ignition** - accompanied by a single chime.
- **Left Front Turn Signal Lamp Out** - accompanied by a single chime.
- **Left Rear Turn Signal Lamp Out** - accompanied by a single chime.
- **Lights On** - accompanied by a single chime.
- **Low Fuel** - accompanied by a single chime.
- **Low Washer Fluid** - accompanied by a single chime.
- **Oil Change Required** - accompanied by a single chime.
- **Press Brake Pedal And Push Button To Start** - if equipped with Keyless Go (KG) and an automatic transmission.
- **Press Clutch Pedal And Push Button To Start** - if equipped with Keyless Go (KG) and a manual transmission.
- **Remote Keyless Entry (RKE) Battery Low** - accompanied by a single chime.
- **Right Front Turn Signal Lamp Out** - accompanied by a single chime.
- **Right Rear Turn Signal Lamp Out** - accompanied by a single chime.
- **Turn Signal On** - accompanied by a continuous warning chime if the vehicle is driven more than 1.6 kilometers (1 mile) with either turn signal ON.

COMPASS/TEMPERATURE/TRIP COMPUTER

Compass heading and outside temperature are displayed on the Instrument Cluster (IC) TFT display. One of eight compass headings to indicate the direction the vehicle is facing (N, S, E, W, NE, NW, SE, SW) and one of 15 compass variance settings can be programmed. Outside temperature is displayed in °C (degrees Celsius) or °F (degrees Fahrenheit).

Press and release the **MENU** button until one of the following trip functions displays in the EVIC:

- **Fuel Economy**
- **Trip Info**
- **Vehicle Speed**

Press the **STEP** button to cycle through all of the trip computer functions.

The trip functions mode displays the following information:

- **Average Fuel Economy** - Displays the average fuel economy since the last reset. When the fuel economy is reset, the display will read RESET or show dashes for two seconds. Then the history information will be erased and the averaging will continue from the last fuel average reading before the reset.
- **Distance To Empty (DTE)** - Displays the estimated distance that can be traveled with the fuel remaining in the tank. This estimated distance is determined by a weighted average of the instantaneous and average fuel economy, along with the current level of fuel in the tank. DTE cannot be reset through the **RESET** button. When the DTE value is less than 48 kilometers (30 miles) estimated driving distance, the DTE display will change to a text display of LOW FUEL. This display will continue until the vehicle runs out of fuel. Adding a significant amount of fuel to the vehicle will turn OFF the LOW FUEL text and a new DTE value will display.
- **Elapsed Time** - When the ignition switch is in the ACC position a display indicates the total elapsed time since the last RESET. Elapsed time will increment when the ignition switch is in the ON or START positions.
- **Trip A or Trip B** - Displays the mileage accumulated since the last RESET when the ignition switch is in the ON or ACC position.
- **Display Units Of Measure In:** - To make your selection, press and release the **RESET** button until **MPH** or **km/h** appears.

RESET will only occur while a function that can be reset is being displayed. Press and release the **RESET** button once to clear the function being displayed. To reset all functions that can be reset (global reset), press and release the **RESET** button a second time within 3 seconds of resetting the currently displayed function. **Reset ALL** will display during this 3 second window.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The Electronic Vehicle Information Center (EVIC) control switch pod (1) is located in the left horizontal spoke of the steering wheel spoke bezel. This switch has up to six push buttons. Four of the push buttons are used on all vehicles equipped with the EVIC. Two additional push buttons are found on vehicles equipped with the optional Uconnect™ Hands-Free Communication System. The only visible components of the switch pod are the switch push buttons and a decorative bezel around the push buttons, which stands slightly proud of the steering wheel spoke bezel. The remainder of the switch pod including its mounting provisions (2) and its electrical connection (3) are concealed beneath the spoke bezel.

The switch pod housing and push buttons are constructed of molded plastic. Each of the push buttons has white International Control and Display Symbol graphics or text applied to it, which clearly identify the function of each push button. The switch pod is secured through three integral mounting tabs to mounting bosses on the back of the spoke bezel by three screws. A connector receptacle integral to the inboard end of the switch housing connects the EVIC switch pod to the Local Interface Network (LIN) slave node circuitry integral to the cruise control switch pod and to the vehicle electrical system through a dedicated take out and connector of the steering wheel wire harness.

The EVIC control switch pod cannot be adjusted or repaired. If any function of the switch is ineffective or damaged, the entire switch pod unit must be replaced.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Position the switch pod and the mounting adapter plate (4) to the back of the front bezel.
2. Install and tighten the screws (3) that secure the mounting adapter plate and the switch to the bezel.
3. Position the spoke bezel assembly close enough to the steering wheel and connect the electrical connector.
4. Engage the lip on the inboard side of the bezel under the edge of the driver airbag trim cover.
5. Position the spoke bezel, mounting adapter plate and pod as a unit to the steering wheel. Be certain that the steering wheel wire harness is not pinched.
6. From the back of the steering wheel (1), install and tighten the screw (3) that secures the bezel assembly to the steering wheel spoke.
7. Connect the battery negative cable.

OPERATION

The Electronic Vehicle Information Center (EVIC) control switch pod is a resistor multiplexed unit that receives source current from and provides hard wired inputs to the Local Interface Network (LIN) slave node integral to the speed control switch pod in the right spoke of the steering wheel spoke bezel. The LIN slave node communicates the switch states of the EVIC control switch pod, the remote radio switches, the horn switch and the heated steering wheel sensor (if equipped) over the LIN data bus to the LIN master node integral to the Steering Angle Sensor (SAS) on the back of the clockspring case. The SAS is also a gateway to the Controller Area Network (CAN) data bus.

The EVIC control switch pod contains four push buttons whose functions are:

- **Back** - Pressing and releasing the Back push button returns you to the previous sub menu or main menu.
- **Down Arrow** - Pressing and releasing the Down Arrow push button allows the operator to scroll downward through the various EVIC main menus and sub menus.
- **Right Arrow** - Pressing and releasing the Right Arrow (Select) push button allows the operator to navigate, select and reset items or settings in the currently displayed EVIC main menu or sub menu. Pressing and holding the Right Arrow (Select) push button for two seconds provides a global reset of all of those EVIC features that can be reset, whether currently displayed or not.
- **Up Arrow** - Pressing and releasing the Up Arrow push button allows the operator to scroll upward through the various EVIC main menus and sub menus.

For vehicles equipped with the Uconnect™ Hands-Free Communication System, the EVIC control switch pod contains two additional switch push buttons whose functions are:

- **VR (Voice Recognition)** - This switch button activates the Uconnect™ Voice Command system.
- **Phone** - This switch push button activates the Uconnect™ Hands-Free Phone system.

The LIN slave node circuitry of the speed control switch pod provides current for all of the switches and sensors on the rotating steering wheel as well as for the Light Emitting Diode (LED) back lighting of both the speed control and the EVIC control switch pods. The SAS continually monitors all of the hard wired speed control switch circuits as well as the LIN bus data. The SAS will store a Signal Not Available (SNA) code for any LIN bus input errors. The SAS also communicates with other electronic modules over the CAN data bus. Therefore, any SAS DTC information can be retrieved using a diagnostic scan tool connected to the Data Link Connector (DLC).

The analog resistor multiplexed circuits of the EVIC control switch pod as well as the hard wired circuits between the switch pod and the speed control switch pod may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the LIN slave or master nodes, the SAS or the electronic controls and communication between modules and other devices that provide some features of the EVIC system. The most reliable, efficient, and accurate means to diagnose the EVIC switch pod, the LIN slave or master nodes, the SAS or the electronic controls and communication related to EVIC system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

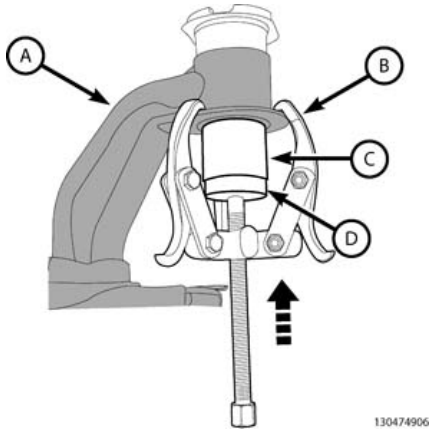
1. Remove the engine cradle crossmember. (Refer to 13 - Frame and Bumpers/Frame /CROSSMEMBER, Front Suspension/Removal)
2. As an installation reference, carefully mark location of isolator (3) requiring removal on crossmember (1) (around isolator can flange) using a marker or crayon. **Do not use a scratch awl to mark location.**

NOTE: Prior to using special tools, lubricate OTC® three jaw puller 1026 or equivalent (B) threads to provide ease of use and promote tool longevity.



3. Assemble tools over isolator crossmember assembly as shown:

A. Crossmember
B. OTC® three jaw puller 1026
C. Remover, Bushing 9334-4
D. Press Plug 9678

4. Tighten OTC® three jaw puller 1026 or equivalent (A) screw-drive, pressing isolator out of the crossmember (A).

2014 Dodge JC - DODGE JOURNEY

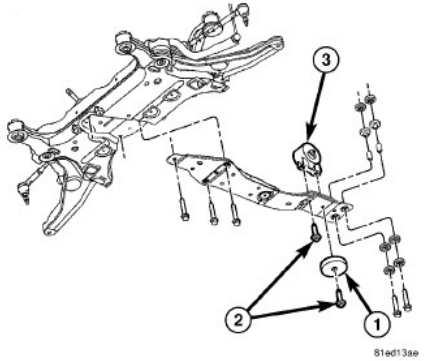
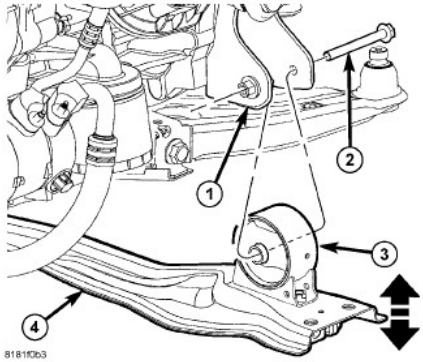
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Install the front engine mount (3) on the crossmember. Install the mounting bolts (2) and damper (1). Tighten the bolts to 50 N·m (37 ft. lbs.).
2. Position the fore-aft crossmember in the engine compartment and install the mounting bolts. Tighten the forward mounting bolts at the radiator support to 55 N·m (41 ft. lbs.). Tighten the rearward mounting bolts at the suspension crossmember to 55 N·m (41 ft. lbs.).



3. Install the front engine mount thru-bolt (4). Tighten the bolt to 60 N·m (44 ft. lbs.).
4. If equipped, install the engine belly pan.
5. Lower the vehicle.



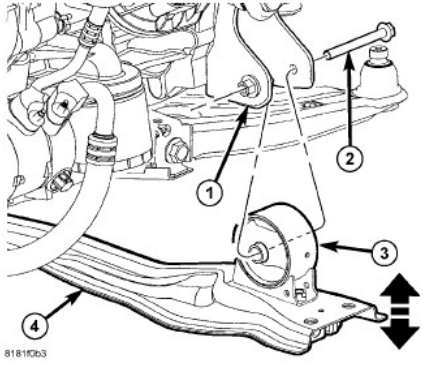
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

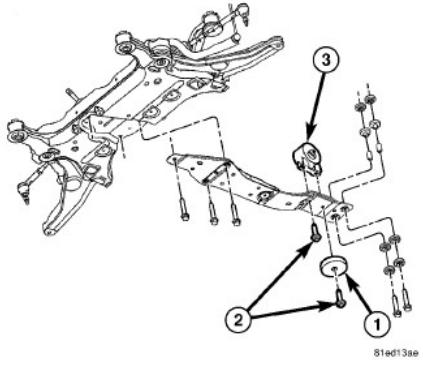
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Raise and support the vehicle (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure) .
2. If equipped, remove the engine belly pan.
3. Remove the front engine mount thru-bolt (2).



4. Remove the fore-aft crossmember forward mounting bolts at the radiator support.
5. Remove the fore-aft crossmember rearward mounting bolts at the crossmember.
6. Remove the fore-aft crossmember.
7. Remove the front engine mount mounting bolts (2) and damper (1). Remove the mount (3) from the crossmember.



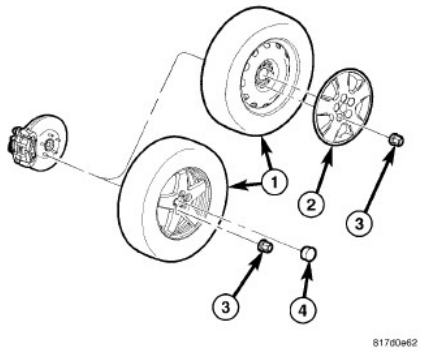
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

REMOVAL

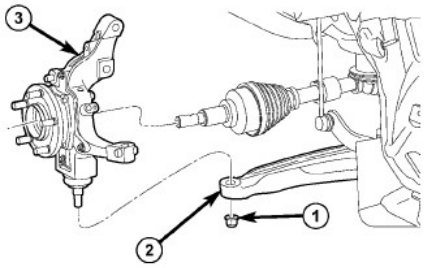
Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)
2. On each side of the vehicle, remove the wheel mounting nuts (3), then the front tire and wheel assembly (1).



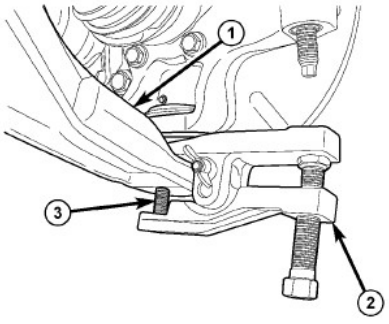
817d0e62

3. On each side of the vehicle, remove the nut (1) attaching the lower ball joint to the lower control arm (2).



819b8498

4. On each side of the vehicle, release the lower ball joint (3) from the lower control arm (1) using Remover (2), Special Tool 9360 . Do not lift the knuckle out of the lower control arm at this time.



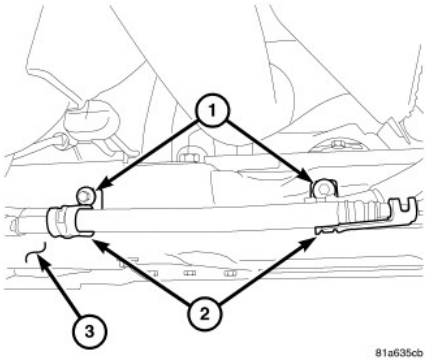
81a30701

5. If equipped, remove the engine belly pan.

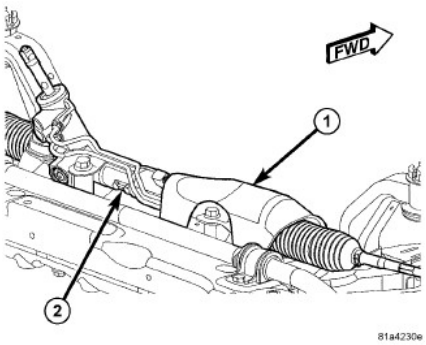
6. Remove the fore/aft crossmember. (Refer to 13 - Frame and Bumpers/Frame/CROSSMEMBER - Removal)

7. Remove the rear engine mount. (Refer to 09 - Engine/Engine Mounting/INSULATOR, Engine Mount - Removal)

8. Remove the screws (1) securing the power steering hose routing clamps (2) to the rear of the crossmember.

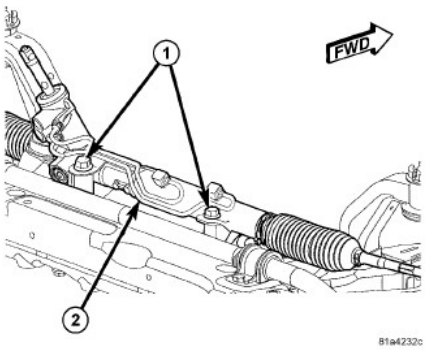


9. Remove the screws and push-pins securing the heat shield (1) over the right side of the steering gear (2).

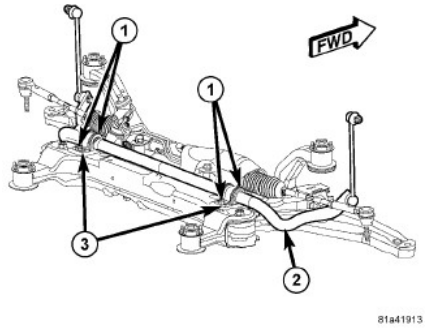


10. Remove the two bolts (1) securing the steering gear (2) to the crossmember.

11. Support the steering gear using a bungee cord or other to keep the steering gear from lowering when the crossmember is lowered.



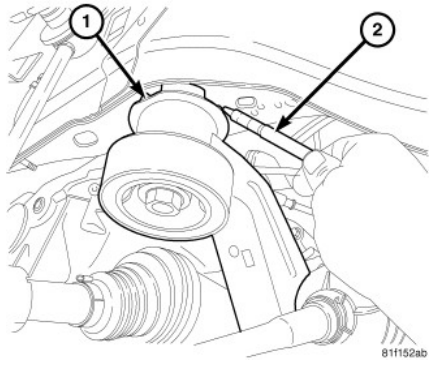
12. Remove the screws (1) securing the stabilizer bushing retainers (3) to the crossmember.



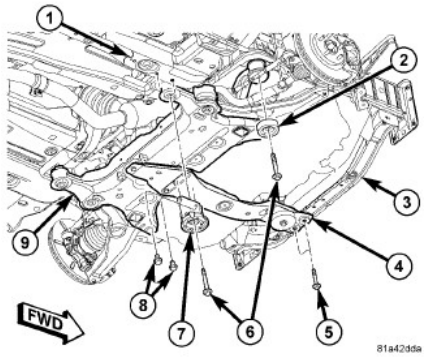
NOTE:

Before lowering the front suspension crossmember, the location of the crossmember must be marked on the body of the vehicle. Do this so the crossmember can be relocated, upon reinstallation, against the body of vehicle in the same location as before removal. If the front suspension crossmember is not reinstalled in exactly the same location as before removal, the preset front wheel alignment settings (caster and camber) may be lost.

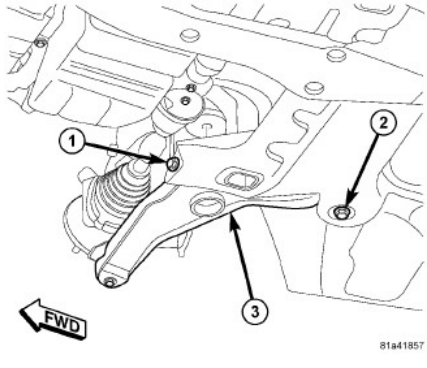
13. Using a crayon or marker (2) that will not break the paint surface, mark the location of the front crossmember (1) on the body near each mounting bolt. **Do not use any type of sharp instrument that will damage the underbody of the vehicle.**



14. Support the crossmember (9) with a transmission jack. Secure the crossmember to the jack.
15. Remove the four mounting bolts (6) securing the front crossmember (9) to the body.
16. Remove the mounting screws (8) securing the front crossmember reinforcement brackets (7) (one each side of vehicle) to the body (1). Remove the brackets.
17. Slowly lower the crossmember and control arms to a comfortable working height using the jack.



18. To remove each lower control arm:
    a. Remove the front bolt (1) attaching the lower control arm (3) to the front suspension crossmember.
    b. Remove the nut on the rear bolt (2) attaching the lower control arm (3) to the front suspension crossmember. Remove the bolt.
    c. Remove the lower control arm (3) from the crossmember.



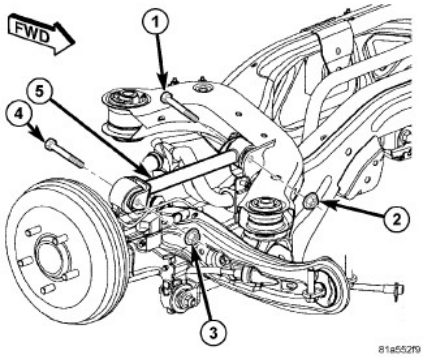
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

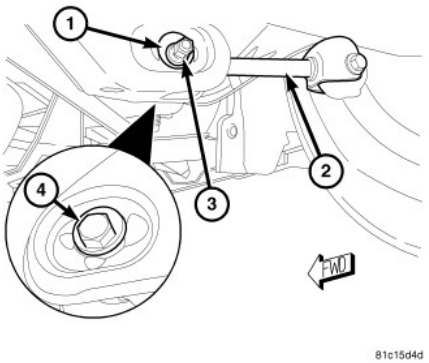
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Support the rear suspension crossmember with a transmission jack. Secure the crossmember to the jack.
2. Slowly raise the crossmember into mounted position using the transmission jack matching the crossmember to the marked locations on the body made during removal. As the crossmember is raised, guide the rear suspension components into place.
3. Install the four mounting bolts (rear bolts have stud heads) securing the crossmember to the body. Tighten the crossmember mounting bolts to 95 N·m (70 ft. lbs.).
4. Position the crossmember reinforcement brackets (one each side of vehicle) over the crossmember rear mounting bolt head-studs and install the mounting nuts, but do not tighten at this time.
5. Install the mounting screws securing the crossmember reinforcement brackets to the body. Tighten the screws to 55 N·m (41 ft. lbs.).
6. Tighten the mounting nuts securing the reinforcement brackets to the rear crossmember mounting bolts to 50 N·m (37 ft. lbs.).
7. Remove the transmission jack.
8. On each side of the vehicle, position the upper control arm (5) and install the bolt (1) and nut (2) securing the arm to the crossmember. Do not tighten either upper control arm mounting bolts at this time.

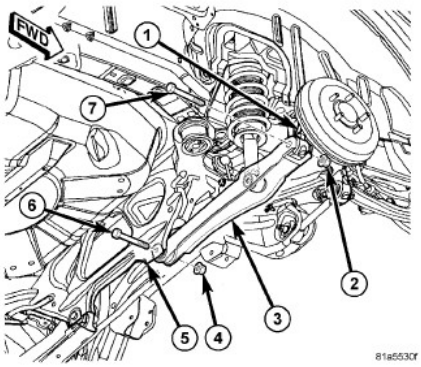


CAUTION: **When installing the cam bolt (4) and washer make sure the cams stay inside the abutments built into the crossmember. Failure to do so can damage the abutments and make toe adjustment difficult.**

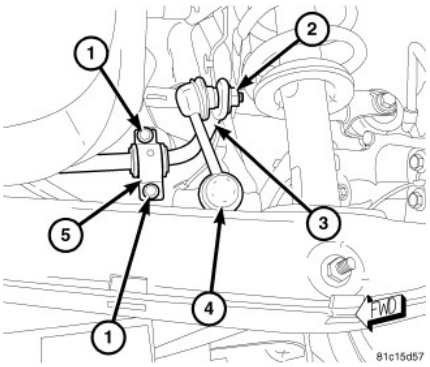


9. On each side of the vehicle:
   a. Position the toe link (2) and install the cam bolt (4) from the front through the crossmember and link. Match the cam on the bolt to the marks made during removal or position the top of the cam to the 12 O'clock position if not available.
   b. Install the cam washer (1) and nut (3) securing the toe link (2) to the crossmember. Do not tighten at this time.

10. On each side of the vehicle, position the lower control arm (3) and install the bolt (6) and nut (4) securing the lower control arm to the crossmember (5). Do not tighten nut and bolt at crossmember or knuckle at this time.



NOTE: When installing the stabilizer bar on a vehicle with all-wheel-drive, position the bar so that the bar loops over the axle half shafts once installed, not under the axle half shafts.



11. Position the stabilizer bar (3) on the rear crossmember.

CAUTION: **Before installing the screws in the following step, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**

12. Install the two retainers (5 - right side shown) over the cushions at the mounting holes and install the retainer screws (1). Do not tighten the screws at this time.

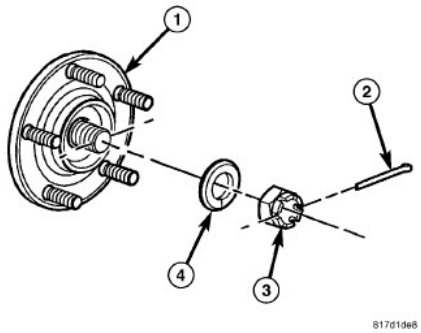
CAUTION: **Before installing the nut in the following step, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**

13. On each side of the vehicle, install the stabilizer link (4) upper stud in the end of the stabilizer bar (3). Install the nut (2) on the upper stud and while holding the stabilizer link stud stationary, tighten the nut to 48 N·m (35 ft. lbs.).

14. On each side of the vehicle, tighten the stabilizer bar retainer screws (1) to 25 N·m (18 ft. lbs.).

NOTE: Always install a new hub nut. The original hub nut is one-time use only and should be discarded when removed.

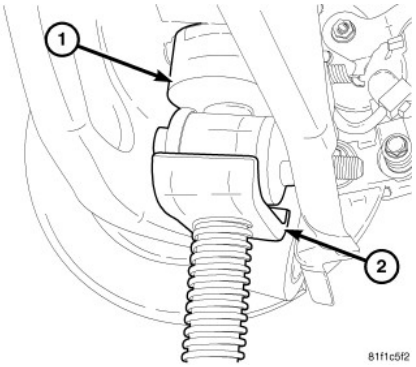
15. If equipped with all-wheel-drive, slide the half shaft into the hub and bearing on each side of the vehicle and hand-start the washer and hub nut (3) Support the shafts to keep them from overextending the joints.



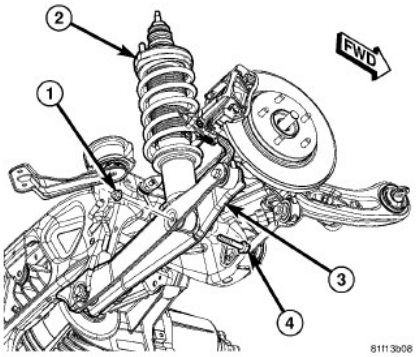
16. If equipped with all-wheel-drive, install the rear driveline module. In place of using a drive-on hoist, place jacks under the outboard ends of the lower control arms and adjust the rear suspension height at the hub and bearings to simulate curb riding height. (Refer to 03 - Differential and Driveline/Rear Driveline Module - Removal) Once the rear driveline module is installed, remove the jacks.

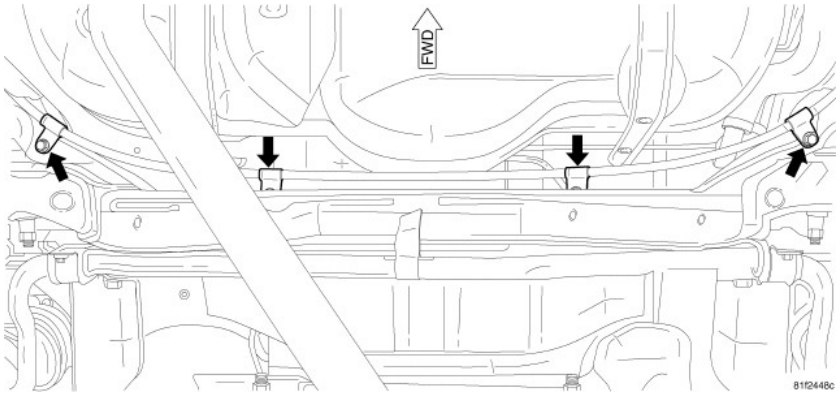
17. On each side of the vehicle, if equipped with load-leveling shocks, place a jack (2) against the lower shock eye and support the lower end of the shock

assembly (1). Lift the shock assembly using the jack until the hole in the lower shock eye lines up with that in the lower control arm.



18. On each side of the vehicle, install the mounting bolt (4) and nut (1) fastening the shock assembly (2) to the lower control arm (3). Do not tighten at this time.

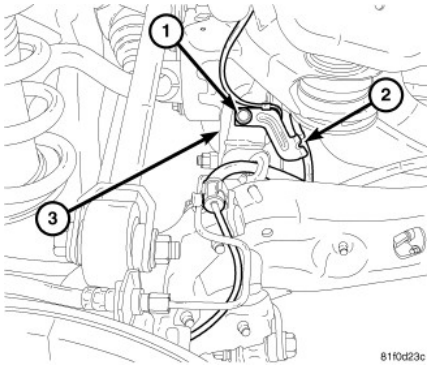




19. Position the four parking brake cable routing clamps along the front of the rear crossmember and install the screws. Tighten the screws to 6 N·m (55 in. lbs.)..

20. Install the exhaust system. (Refer to 11 - Exhaust System/PIPE, Exhaust - Installation) .

21. On each side of the vehicle, attach the wheel speed sensor routing clamp (2) to the rear suspension crossmember (3) using the mounting screw (1). Tighten the mounting screw to 20 N·m (15 ft. lbs.).

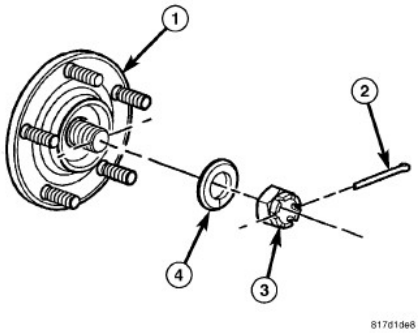


22. While a helper applies the brakes to keep the hub (1) from rotating, on each side of the vehicle:

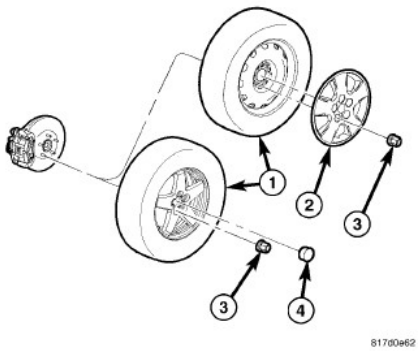
    a. Tighten the hub nut (3) to 245 N·m (181 ft. lbs.).

    b. Insert the cotter pin (2) through the notches in the nut and the hole in half shaft. If the notches in the nut do not line up with the hole in the half shaft, continue to tighten the nut until they do. **Do not loosen the nut.**

    c. Wrap the cotter pin (2) ends tightly around the lock nut.



23. On each side of the vehicle, install tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).



24. Lower the vehicle.

25. Position the vehicle on an alignment rack/drive-on lift. Raise the vehicle as necessary to access mounting bolts and nuts.

26. Tighten the lower control arm mounting bolt nut at the crossmember to 105 N·m (77 ft. lbs.).

27. Tighten the lower control arm mounting bolt nut at the knuckle to 105 N·m (77 ft. lbs.).

28. Tighten the shock assembly lower mounting bolt nut to 99 N·m (73 ft. lbs.).

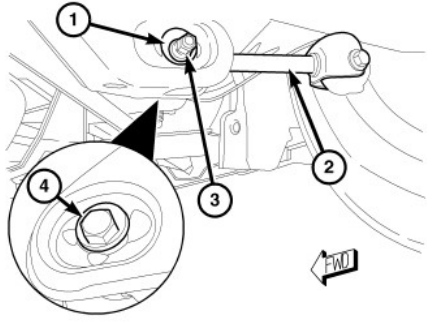
29. Tighten the upper control arm mounting bolt nut at the crossmember to 105 N·m (77 ft. lbs.).

30. Tighten the upper control arm mounting bolt nut at the knuckle to 105 N·m (77 ft. lbs.).

31. Tighten the toe link mounting bolt nut at the knuckle to 105 N·m (77 ft. lbs.).

32. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)

33. Once rear toe is set, while holding the cam bolt (4) head stationary, tighten the toe link mounting cam bolt nut (3) to 100 N·m (74 ft. lbs.).



2014 Dodge JC - DODGE JOURNEY

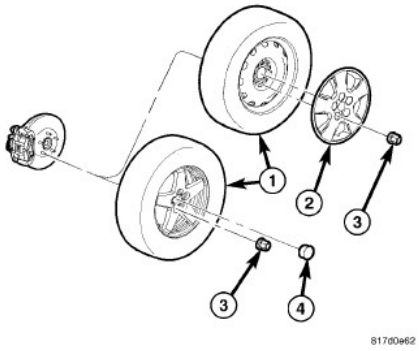
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

REMOVAL

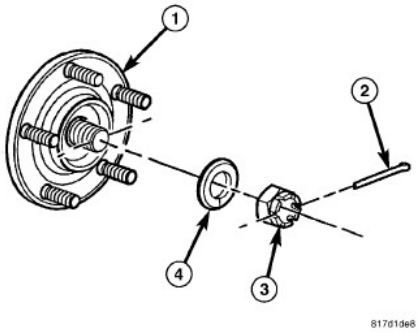
Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)

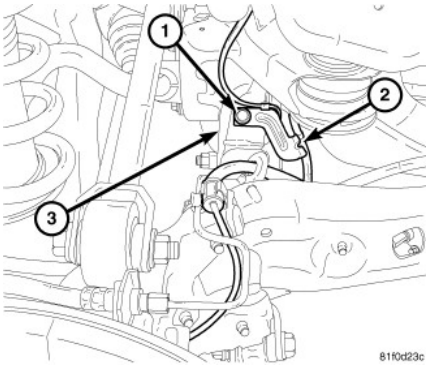
2. On each side of the vehicle, remove the wheel mounting nuts (3), then the front tire and wheel assembly (1).



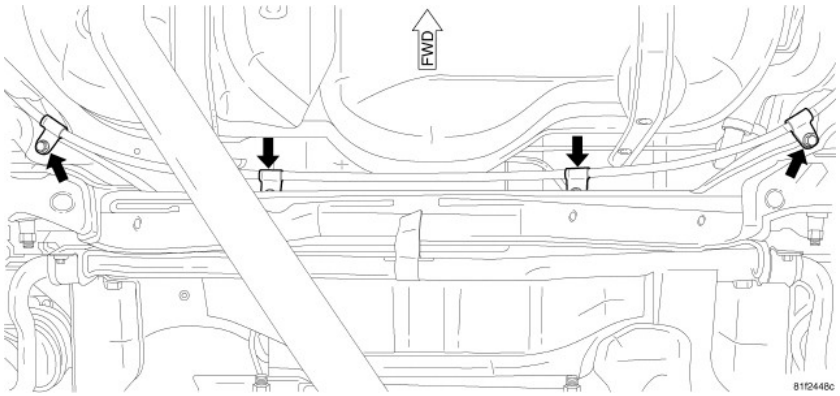
3. If equipped with all-wheel-drive, remove the cotter pin (2) from the hub nut (3) on the end of the axle half shaft. While a helper applies the brakes to keep the hub (1) from rotating, remove the hub nut (3) and washer (4) from the axle half shaft.



4. On each side of the vehicle, remove the screw (1) fastening the wheel speed sensor routing clamp (2) to the rear suspension crossmember (3).

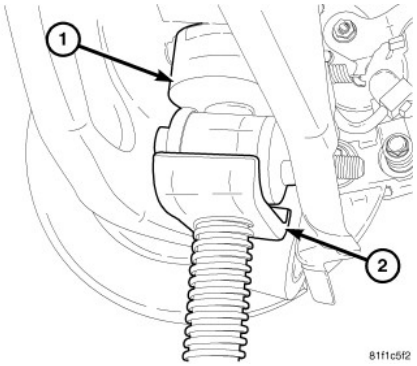


5. Remove the exhaust system from the vehicle. (Refer to 11 - Exhaust System/PIPE, Exhaust - Removal)

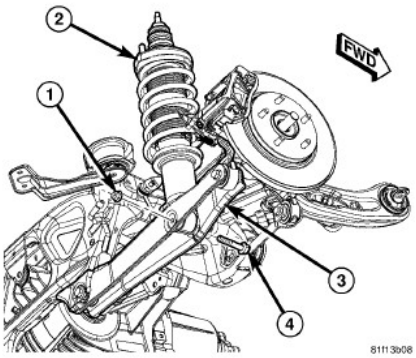


6. Remove the screws securing the four right rear parking brake cable routing clamps to the rear crossmember .

7. On each side of the vehicle, if equipped with load-leveling shocks, support the lower shock (1) with a jack (2) using just enough force to allow easy removal of the lower shock mounting bolt in the following step. Lower the jack following bolt removal.



8. On each side of the vehicle, remove the lower shock mounting nut (1) and bolt (4).



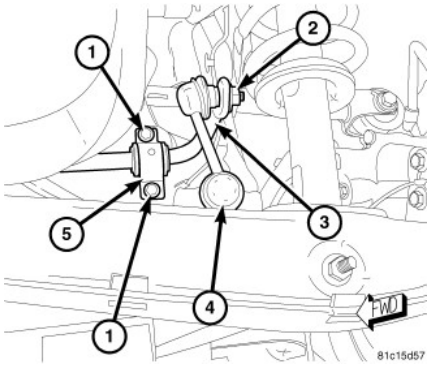
9. If equipped with all-wheel-drive, remove the rear driveline module, but instead of using a drive-on hoist, place jacks under the outboard ends of the lower control arms and adjust the rear suspension height at the hub and bearings to simulate curb riding height. (Refer to 03 - Differential and Driveline/Rear Driveline Module - Removal) Once the rear driveline module is removed, remove the jacks.

10. If equipped with all-wheel-drive, slide the half shaft out of the hub and bearing on each side of the vehicle and remove it.

11. On each side of the vehicle, while holding the stabilizer bar link upper stud stationary, remove the nut (2) securing the link (4) to the stabilizer bar (3).

12. On each side of the vehicle, remove the screws (1) securing the stabilizer bar retainer (5) to the crossmember.

13. Remove the stabilizer bar (3) from the vehicle.

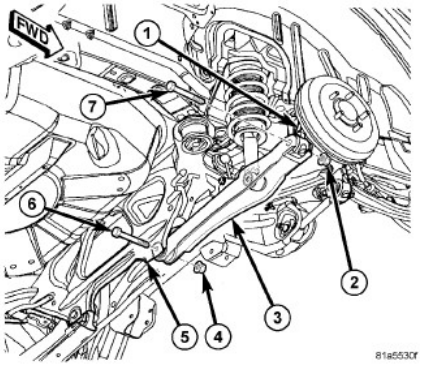


14. On each side of the vehicle:

    a. Loosen (do not remove) the nut (2) and bolt (7) securing the lower control arm (3) to the knuckle (1).

    b. Remove the nut (4) and bolt (6) securing the lower control arm (3) to the rear crossmember (5).

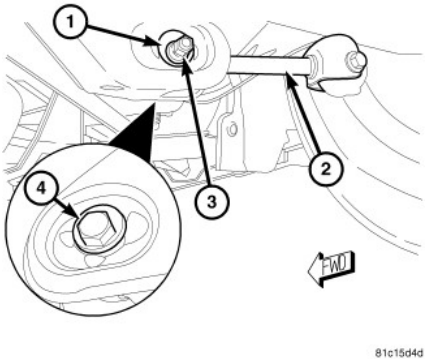
    c. Swing the lower control arm down away from the rear crossmember.



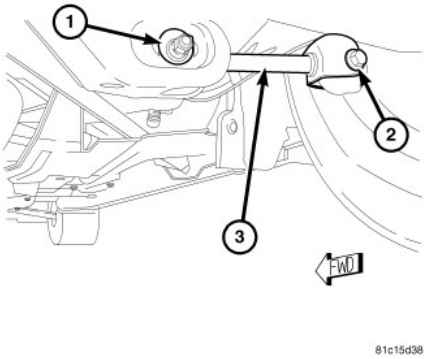
15. On each side of the vehicle:

    a. Mark the position of the cam bolt (4) cams on the crossmember using a paint marker or crayon. Do not use any type marker that will scratch or damage the surface of the crossmember.

    b. While holding the cam bolt (4) head stationary, loosen and remove the toe link mounting cam bolt nut (3) and washer (1). Remove the cam bolt.



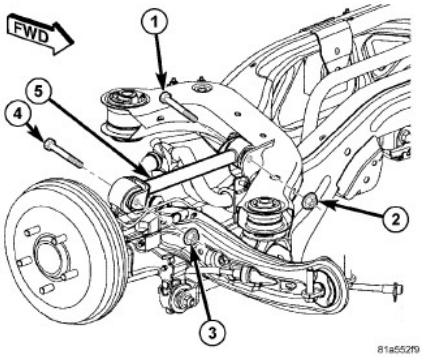
16. On each side of the vehicle, loosen (do not remove) the mounting bolt (2) and nut securing the toe link (3) to the knuckle.



17. On each side of the vehicle:

    a. Loosen (do not remove) the nut (3) and bolt (4) securing the upper control arm (5) to the knuckle.

    b. Remove the nut (2) and bolt (1) securing the upper control arm (5) to the crossmember.



18. On each side of the vehicle, using wire or a bungee cord, support the knuckle to keep it from sagging.

NOTE:

Before lowering the rear suspension crossmember, the location of the crossmember must be marked on the body of the vehicle. Do this so the crossmember can be relocated, upon reinstallation, against the body of vehicle in the same location as before removal. If the crossmember is not reinstalled in exactly the same location as before removal, the rear wheel alignment settings may be lost.

19. Using a crayon or marker that will not break the paint surface, mark the location of the rear suspension crossmember on the body near each mounting bolt. **Do not use any type of sharp instrument that will damage the underbody of the vehicle.**

20. Support the crossmember with a transmission jack. Secure the crossmember to the jack.

21. Remove the two mounting screws securing each crossmember reinforcement bracket (one each side of vehicle) to the body.

22. Remove the mounting nuts securing the crossmember reinforcement brackets to the crossmember rear mounting bolts. Remove the brackets.

23. Remove the four mounting bolts securing the crossmember to the body.

24. Slowly lower the crossmember using the jack.

USE OF HEAT DURING REPAIR

WARNING:

Chrysler Group LLC engineering's position on the use of heat during collision repair is as follows:

- **Any body panel or frame component damaged which is to be repaired and reused, must be repaired using the "cold straightening" method. No heat may be used during the straightening process.**
- **During rough straightening prior to panel replacement, damaged panels or frame components may be heated to assist in body/frame realignment. The application of heat must be constrained to the parts which will be replaced and not allowed to affect any other components.**

This "no heat" recommendation is due to the extensive use of high strength and advanced high strength steels in Chrysler Group LLC products. High-strength materials can be substantially and negatively affected from heat input which will not be obviously known to the repairer or consumer.

Ignoring these recommendations may lead to serious compromises in the ability to protect occupants in a future collision event, reduce the engineered qualities and attributes, or decrease the durability and reliability of the vehicle.

This statement supersedes any previously released information by the Chrysler Group LLC.

Failure to follow these instructions may result in serious or fatal injury.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

WARNINGS

WARNING:

Use an Occupational Safety and Health Administration (OSHA) approved breathing filter, when spraying paint or solvents in a confined area. Failure to follow these instructions may result in possible serious or fatal injury.

- **avoid prolonged skin contact with petroleum or alcohol based cleaning solvents.**
- **do not stand under a hoisted vehicle that is not properly supported on safety stands. Failure to follow these instructions may result in possible serious or fatal injury.**

CAUTION:

When holes are drilled or punched in an inner body panel, verify the depth of space to the outer body panel, electrical wiring or other components. Damage to the vehicle can result.

- **do not weld exterior panels unless combustible material on the interior of vehicle is removed from the repair area. Fire or hazardous conditions, can result.**
- **always have a fire extinguisher ready for use when welding.**
- **disconnect the negative (-) cable clamp from the battery when servicing electrical components that are live when the ignition is off. Damage to electrical system can result.**
- **do not use abrasive chemicals or compounds on painted surfaces. Damage to finish can result.**
- **do not use harsh alkaline based cleaning solvents on painted or upholstered surfaces. Damage to finish or color can result.**
- **do not hammer or pound on plastic trim panel when servicing interior trim. Plastic panels can break.**

Restraint Warnings

WARNING:

To avoid potential physical injury, or damage to sensitive electronic circuits and systems, always disconnect and isolate the battery negative (ground) cable and the positive cable, then ground the positive cable to discharge the ORC capacitor before performing any welding operations on the vehicle. Failure to take the proper precautions could result in accidental airbag deployment, possible damage to the Supplemental Restraint System (SRS) circuits and components, and possible damage to other electronic circuits and components. Whenever a welding process is being performed within 30 cm (12 in) of an electronic module/harness, then that module/harness should be relocated out of the way, or disconnected. Always protect against component or vehicle damage from weld spatter by using weld blankets and screens. Failure to follow these instructions may result in serious or fatal injury.

WARNING:

To avoid serious or fatal injury on vehicles equipped with the Supplemental Restraint System (SRS), never attempt to repair the electrically conductive circuits or wiring components related to the SRS for which there is no MOPAR wiring repair kit. It is important to use ONLY the recommended splicing kit and procedure. For applicable and available MOPAR wiring repair kits, please visit the MOPAR Connector Web Site at the following address on the internet: (http://dto.vftis.com/mopar/disclaimer.asp). Inappropriate repairs can compromise the conductivity and current carrying capacity of those critical electrical circuits, which may cause SRS components not to deploy when required, or to deploy when not required. Only minor cuts or abrasions of wire and terminal insulation where the conductive material has not been damaged, or connector insulators where the integrity of the latching and locking mechanisms have not been compromised may be repaired using appropriate methods.

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

WARNING:

To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, Occupant Classification System (OCS), seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to follow these instructions may result in accidental airbag deployment.

WARNING: **To avoid potential physical injury or damage to sensitive electronic circuits and systems, always disconnect and isolate the battery negative (ground) cable and the positive cable, then ground the positive cable to discharge the Occupant Restraint Controller (ORC) capacitor before performing any welding operations on the vehicle. Failure to take the proper precautions could result in accidental airbag deployment, possible damage to the Supplemental Restraint System (SRS) circuits and components, and possible damage to other electronic circuits and components. Whenever a welding process is being performed within 12 inches (30 centimeters) of an electronic module or wiring harness, then that module or harness should be relocated out of the way, or disconnected. Always protect against component or vehicle damage from weld spatter by using weld blankets and screens.**

WARNING: **To avoid serious or fatal injury, do not attempt to dismantle an airbag unit or tamper with its inflator. Do not puncture, incinerate or bring into contact with electricity. Do not store at temperatures exceeding 93° C (200° F). An airbag inflator unit may contain sodium azide and potassium nitrate. These materials are poisonous and extremely flammable. Contact with acid, water, or heavy metals may produce harmful and irritating gases (sodium hydroxide is formed in the presence of moisture) or combustible compounds. An airbag inflator unit may also contain a gas canister pressurized to over 17.24 kPa (2500 psi). Failure to follow these instructions may result in possible serious or fatal injury.**

WARNING: **To avoid serious or fatal injury when handling a seat belt tensioner retractor. Exercise proper care to keep fingers out from under the retractor cover and away from the seat belt webbing where it exits from the retractor cover. Failure to follow these instructions may result in possible serious or fatal injury.**

WARNING: **To avoid serious or fatal injury, replace all Supplemental Restraint System (SRS) components only with parts specified in the Chrysler Mopar® Parts Catalog. Substitute parts may appear interchangeable, but internal differences may result in inferior occupant protection.**

WARNING: **To avoid serious or fatal injury, the fasteners, screws, and bolts originally used for the Supplemental Restraint System (SRS) components must never be replaced with any substitutes. These fasteners have special coatings and are specifically designed for the SRS. Anytime a new fastener is needed, replace it with the correct fasteners provided in the service package or specified in the Chrysler Mopar® Parts Catalog.**

WARNING: **To avoid serious or fatal injury when a steering column has an airbag unit attached, never place the column on the floor or any other surface with the steering wheel or airbag unit face down. Failure to follow these instructions may result in possible serious or fatal injury.**

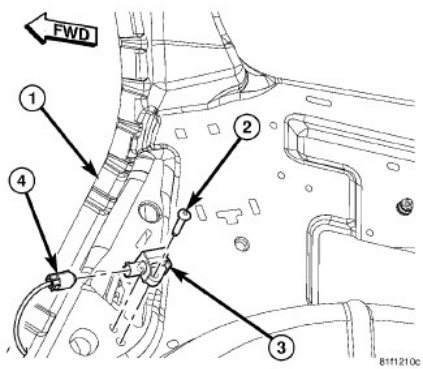
SIDE - C-PILLAR

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, never strike or drop the side impact sensor, as it can damage the impact sensor or affect its calibration. The side impact sensor enables the system to deploy the side Supplemental Restraint System (SRS) components. If an impact sensor is accidentally dropped during service, the sensor must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper side SRS component deployment.**

NOTE: The front and the B, C or D-pillar side impact sensors are interchangeable.



1. Position the side impact sensor (3) to the lower C-pillar (1).
2. Align the anti-rotation pin on the base of the sensor with the clearance hole in the lower C-pillar, then press on the sensor firmly and evenly to snap the pin into place.
3. Install and tighten the screw (2) that secures the side impact sensor to the lower C-pillar. Tighten the screw to 9 N·m (80 in. lbs.).
4. Reconnect the body wire harness connector (4) to the side impact sensor on the lower C-pillar.
5. Reinstall the quarter trim panel onto the lower C-pillar. (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Installation) .
6. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

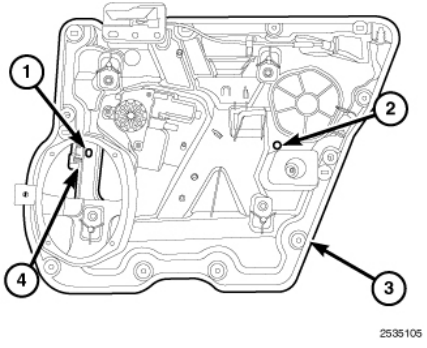
1. Remove door trim panel and re-install the window switches, if equipped. (Refer to 23 - Body/Doors - Rear/PANEL, Rear Door Trim - Removal)
2. Remove the interior window trim molding. (Refer to 23 - Body/Doors - Rear/MOLDING - Removal)
3. Remove the door speaker. (Refer to 08 - Electrical/8A - Audio and Video/SPEAKER - Removal)
4. Drill a hole large enough to get a small punch through into the carrier plate (2).



5. Lower glass to approximately mid position and line up the glass lift plates (4) with the holes (1 and 2).
6. Using a punch or equivalent, press tabs releasing glass from window regulator (1 and 2).
7. Remove glass from channel by rotating the front of the glass up 90° and carefully pulling the glass up and out of the door.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

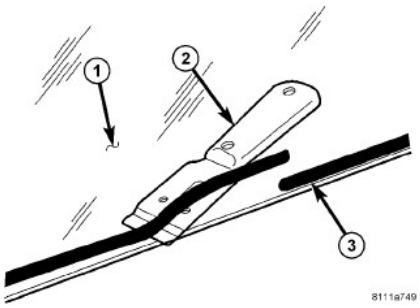
WARNING: **Allow the urethane at least 24 hours to cure before returning the vehicle to use.**

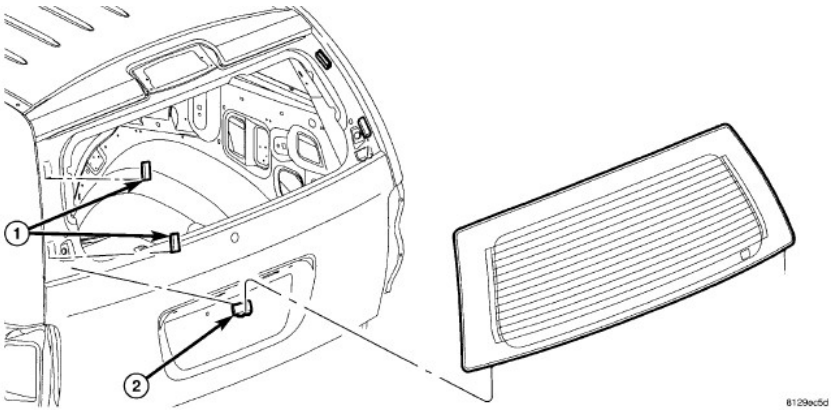
CAUTION: **Roll down the left and right front door glass and open the rear glass slider (if available) before installing backlite to avoid pressurizing the passenger compartment if a door is slammed before urethane is cured. Water leaks can result.**

NOTE: The backlite fence should be cleaned of most of its old urethane bonding material. A small amount of old urethane, approximately 1-2 mm in height, should remain on the fence. Do not grind off or completely remove all old urethane from the fence, the paint finish and bonding strength will be adversely affected. Support spacers should be replaced with new parts. Replace any missing or damaged spacers around the perimeter of the liftgate opening.

Glass Preparation - Installing A Previously Installed Backlite

1. Before proceeding with the following repair procedure, review all warnings and cautions. (Refer to 23 - Body/Stationary Glass - Warning)
2. Level old bead of backlite adhesive (3) to a thickness of approximately 1 mm (0.04 in.) and remove loose adhesive.





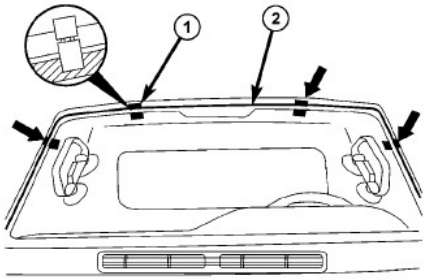
3. Apply four new spacers (1) to the liftgate frame and place them 55 mm in from the window opening; 70 mm from the upper edge and 150 mm from the lower edge.
4. Install the lower spacers (2) to the backlite approximately 25 mm (1.0 in) from each side of the glass.

NOTE: Remove the lower spacers 2 hours after installation of the glass.

5. Position backlite in center of liftgate opening and resting on the side and lower spacers.

6. Apply adhesive tape strips (1) around the perimeter of the liftgate opening to aid in installation.

NOTE: Windshield installation shown, backlite similar.

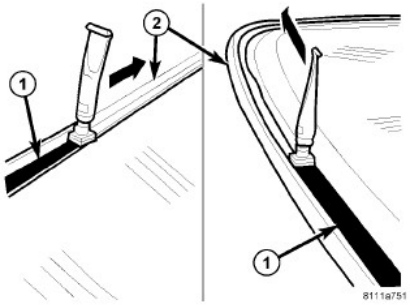


8111a741

7. Verify the backlite gap is parallel to with the liftgate opening.

8. Cut tape with a sharp knife and remove backlite.

NOTE: Typical primer installation shown.



8111a751

9. Clean and dry area of glass (2) to be re-glued with a suitable glass preparation solvent and rag.

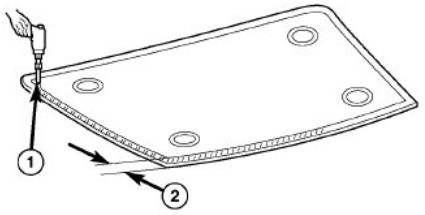
10. Using a flash light, verify that glass primer is without damage.

11. Re-prime any damaged area. If old adhesive has been exposed for more than 12 hours, entire adhesive area needs to be re-primed.

12. Apply primer (1) around the perimeter of the glass to a width of 15 mm (0.5 in.) (2).

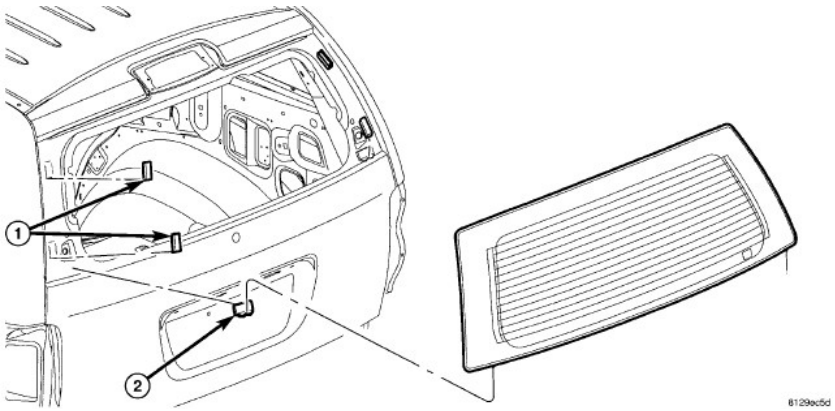
13. Allow primer to air dry for at least 10 minutes.

14. Using a flash light, verify that glass primer is without damage.



8129ec29

Glass Preparation - Installing A New Backlite



1. Apply four new spacers (1) to the liftgate frame and place them 55 mm in from the window opening; 70 mm from the upper edge and 150 mm from the lower edge.

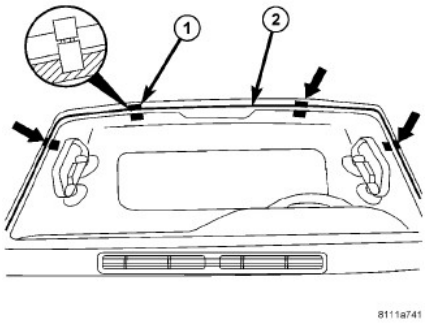
2. Install the lower spacers (2) to the backlite approximately 36 cm (1.0 in) from each side of the glass.

   NOTE: Remove the lower spacers 2 hours after installation of the glass.

3. Position backlite in center of liftgate opening and resting on the side and lower spacers.

4. Apply adhesive tape strips (1) around the perimeter of the liftgate opening to aid in installation.

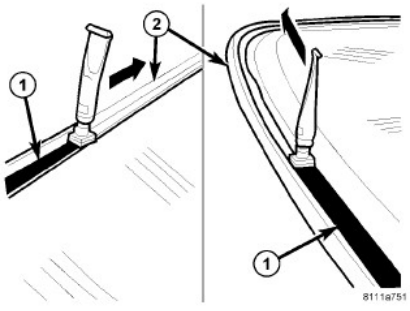
   NOTE: Windshield installation shown, backlite similar.



5. Verify the backlite gap is parallel to with the liftgate opening.

6. Cut tape with a sharp knife and remove backlite.

   NOTE: Typical primer installation shown.



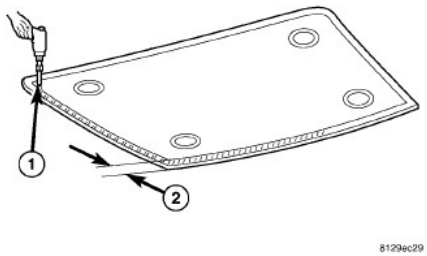
7. Clean and dry area of glass (2) to be re-glued with a suitable glass preparation solvent and rag.

8. Apply primer to gluing surface at backlite seal.

9. Apply primer (1) around the perimeter of the glass to a width of 15 mm (0.5 in.) (2).

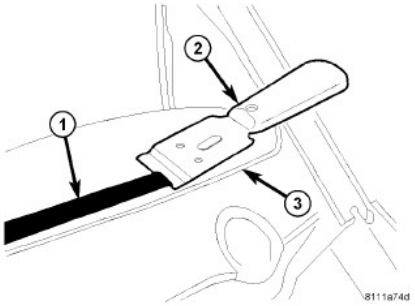
10. Allow primer to air dry for at least 10 minutes.

11. Using a flash light, verify that glass primer is without damage.



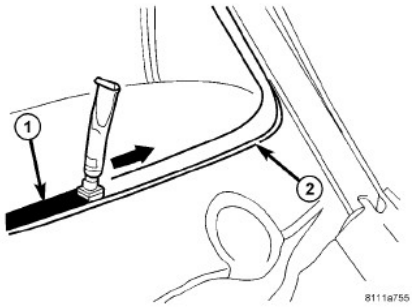
Liftgate Opening Preparation

NOTE: Windshield opening shown, liftgate opening similar.



1. Clean and vacuum liftgate opening.
2. Level old bead of liftgate opening adhesive (1) to a thickness of approximately 1 mm (0.04 in.) and remove loose adhesive.

NOTE: Windshield opening shown, liftgate opening similar.

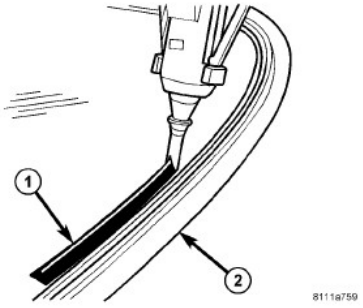


3. Clean and dry area of liftgate opening to be re-glued with a suitable glass preparation solvent and rag.
4. Re-prime any damaged area. If old adhesive has been exposed for more than 12 hours, entire adhesive area needs to be re-primed.
5. Allow primer to air dry for at least 10 minutes.

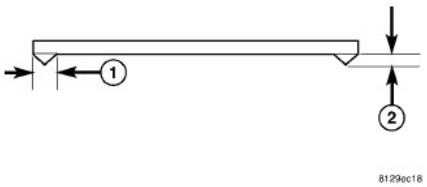
Backlite Installation

1. Apply bead of adhesive (1) with a triangular nozzle directly to the backlite seal starting at bottom in center of the backlite.

CAUTION: **Always apply bead of adhesive to the backlite. Always install the backlite within 5 minutes after applying adhesive.**

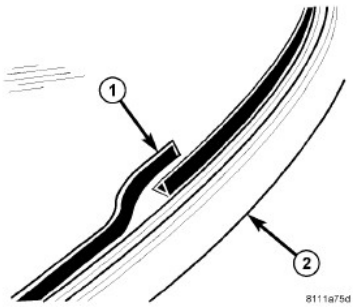


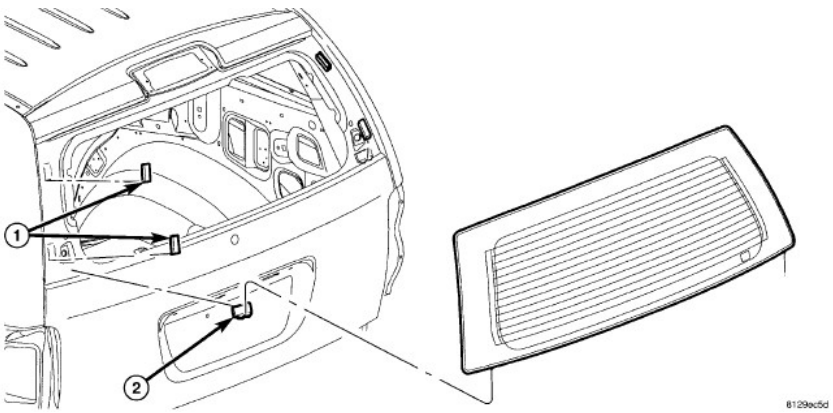
2. Bead dimensions should be approximately 9.5 mm wide (1) by 12.7 mm in height (2).



1 - ADHESIVE WIDTH 9.5 mm (0.375 in)	2 - ADHESIVE HEIGHT 12.7 mm (0.50 in)

3. Allow end of adhesive bead (1) to run out parallel to the start of the bead and smooth ends flush.





4. Lift backlite into place in the center of the liftgate opening and use the tape as a guide to aid installation of the backlite into the center of the cutout.

5. Carefully lay down the backlite and press on.

CAUTION: **It is no longer possible to move the backlite after installation. The backlite should never be pressed into place by more than one person, because the backlite can break if pressed simultaneously on both sides.**

CAUTION: **Roll down the left and right front door glass and open the rear glass slider (if available) before installing backlite to avoid pressurizing the passenger compartment if a door is slammed before urethane is cured. Water leaks can result.**

6. Install the rear wiper arm, if equipped. (Refer to 08 - Electrical/8R - Wipers/Washers/ARM, Wiper - Installation)

7. Install the liftgate trim panels.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **Allow the urethane at least 24 hours to cure before returning the vehicle to use.**

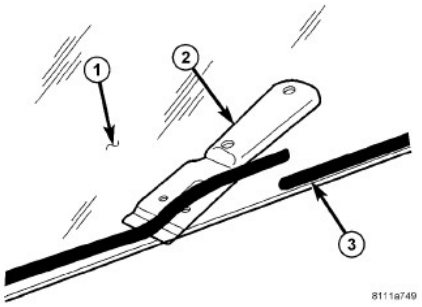
CAUTION: **Roll down the left and right front door glass and open the rear glass slider (if available) before installing quarter glass to avoid pressurizing the passenger compartment if a door is slammed before urethane is cured. Water leaks can result.**

NOTE: The quarter glass fence should be cleaned of most of its old urethane bonding material. A small amount of old urethane, approximately 1-2 mm in height, should remain on the fence. Do not grind off or completely remove all old urethane from the fence, the paint finish and bonding strength will be adversely affected.

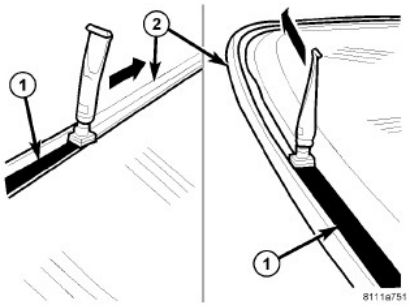
1. Install quarter panel trim. (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Installation)

Glass Preparation - Installing A Previously Installed Quarter Glass

1. Before proceeding with the following repair procedure, review all warnings and cautions. (Refer to 23 - Body/Stationary Glass - Warning)
2. Level old bead of quarter glass adhesive (3) to a thickness of approximately 1 mm (0.04 in.) and remove loose adhesive.



NOTE: Typical primer installation shown.



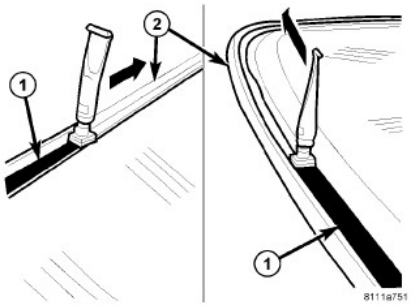
3. Clean and dry area of glass (2) to be re-glued with a suitable glass preparation solvent and rag.
4. Using a flash light, verify that glass primer is without damage.
5. Re-prime any damaged area. If old adhesive has been exposed for more than 12 hours, entire adhesive area needs to be re-primed.
6. Apply primer (1) around the perimeter of the glass to a width of 15 mm (0.5 in.).

NOTE: Make sure the primer does not touch the locating pins and tabs.

7. Allow primer to air dry for at least 10 minutes.
8. Using a flash light, verify that glass primer is without damage.

Glass Preparation - Installing A New Quarter Glass

NOTE: Typical primer installation shown.



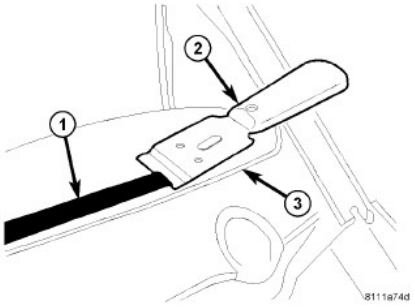
1. Clean and dry area of glass (2) to be re-glued with a suitable glass preparation solvent and rag.
2. Apply primer to gluing surface at quarter glass seal.
3. Apply primer (1) around the perimeter of the glass to a width of 15 mm (0.5 in.) (3).

NOTE: Make sure the primer does not touch the locating pins and tabs (2, 4).

4. Allow primer to air dry for at least 10 minutes.
5. Using a flash light, verify that glass primer is without damage.

Quarter Glass Opening Preparation

NOTE: Windshield opening shown, quarter glass opening similar.

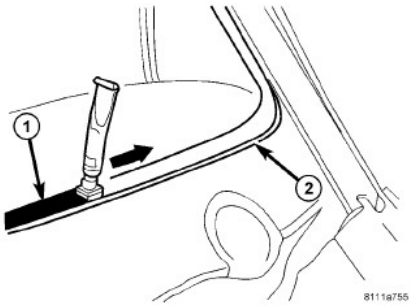


1. Clean and vacuum quarter glass opening.
2. Level old bead of quarter glass opening adhesive (1) to a thickness of approximately 1 mm (0.04 in.) and remove loose adhesive.

NOTE: Windshield opening shown, quarter glass opening similar.

3. Clean and dry area of quarter glass opening to be re-glued with a suitable glass preparation solvent and rag.
4. Re-prime any damaged area. If old adhesive has been exposed for more than 12 hours, entire adhesive area needs to be re-primed.

NOTE: Make sure the primer does not touch the locating pins and tabs.

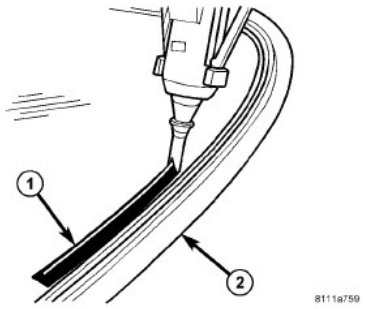


5. Allow primer to air dry for at least 10 minutes.

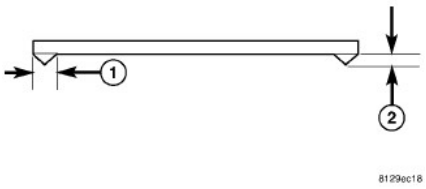
Quarter Glass Installation

1. Apply bead of adhesive (1) with a triangular nozzle directly to the quarter glass seal starting at bottom in center of the quarter glass.

CAUTION: **Always apply bead of adhesive to the quarter glass. Always install the quarter glass within 5 minutes after applying adhesive.**



2. Bead dimensions should be approximately 9.5 mm wide (1) by 12.7 mm in height (2).

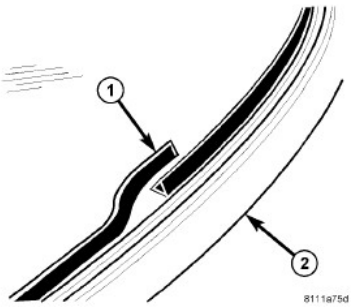


1 - ADHESIVE WIDTH 9.5 mm (0.375 in)	2 - ADHESIVE HEIGHT 12.7 mm (0.50 in)

3. Allow end of adhesive bead (1) to run out parallel to the start of the bead and smooth ends flush.

4. Lift quarter glass into place in the center of the quarter glass opening and install over the alignment tabs and pin.

5. Carefully lay down the quarter glass and press on.



CAUTION: **It is no longer possible to move the quarter glass after installation. The quarter glass should never be pressed into place by more than one person, because the quarter glass can break if pressed simultaneously on both sides.**

CAUTION:

Roll down the left and right front door glass and open the rear glass slider (if available) before installing quarter glass to avoid pressurizing the passenger compartment if a door is slammed before urethane is cured. Water leaks can result.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

WARNING

WARNING:

Do not operate the vehicle within 24 hours of windshield installation. It takes at least 24 hours for urethane adhesive to cure. If it is not cured, the windshield may not perform properly in an accident.

- **Urethane adhesives are applied as a system. Use glass cleaner, glass prep solvent, glass primer, PVC (vinyl) primer and pinch weld (fence) primer provided by the adhesive manufacturer. If not, structural integrity could be compromised.**
- **Chrysler does not recommend glass adhesive by brand. Technicians should review product labels and technical data sheets, and use only adhesives that their manufactures warrant will restore a vehicle to the requirements of FMVSS 212. Technicians should also insure that primers and cleaners are compatible with the particular adhesive used.**
- **Be sure to refer to the urethane manufacturer's directions for curing time specifications, and do not use adhesive after its expiration date.**
- **Vapors that are emitted from the urethane adhesive or primer could cause personal injury. Use them in a well-ventilated area.**
- **Skin contact with urethane adhesive should be avoided. Personal injury may result.**
- **Always wear eye and hand protection when working with glass.**

CAUTION:

Protect all painted and trimmed surfaces from coming in contact with urethane or primers.

Be careful not to damage painted surfaces when removing moldings or cutting urethane around windshield.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The windshield is attached to the window frame (fence) with urethane adhesive. The urethane adhesive is applied cold and seals the surface area between the window opening and the glass. The primer adheres the urethane adhesive to the windshield.

It is difficult to salvage a windshield during the removal operation. The windshield is part of the structural support for the roof. The urethane bonding used to secure the windshield to the fence is difficult to cut or clean from any surface. If the rubber seals are set in urethane, it would also be unlikely they could be salvaged. Before removing the windshield, check the availability of the windshield and seals from the parts supplier.

2014 Dodge JC - DODGE JOURNEY

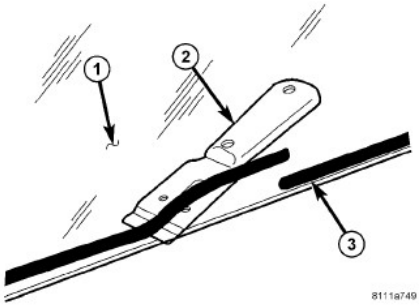
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **Do not operate the vehicle within 24 hours of windshield installation. It takes at least 24 hours for urethane adhesive to cure. If it is not cured, the windshield may not perform properly if the vehicle is in an accident.**

CAUTION: **To help prevent water leaks, partially roll down the left and right door glass before installing the windshield. This avoids pressurizing the passenger compartment if a door is slammed before the urethane is cured.**

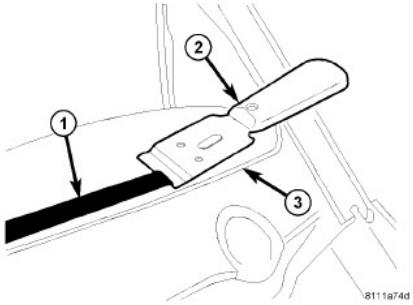


1. If the windshield (1) is being reused, remove as much of the original urethane (3) as possible from the glass surface using a razor knife (2).

CAUTION: **To prevent corrosion, do not damage paint on windshield fence when removing original urethane.**

CAUTION: **The windshield fence should be cleaned of most of its old urethane adhesive. A small amount of old urethane, approximately 1 mm (.039 in.) in height should remain on the fence. Do not completely remove all old urethane from the fence, the paint finish and bonding strength will be adversely affected.**

CAUTION: **Support spacers located near the cowl at the bottom of the windshield fence should be replaced with new spacers. Replace any missing or damaged spacers around the perimeter of the windshield fence.**



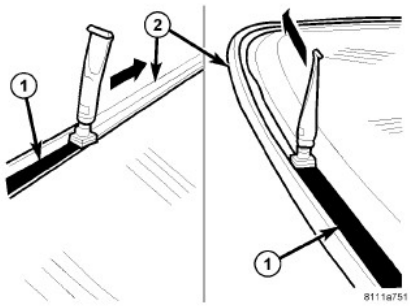
2. Using a razor knife (2), level the original bead of urethane (1) on the windshield fence (3) to a thickness of approximately 1 mm (0.04 in.) and remove any damaged adhesive backed spacers.
3. Install new adhesive backed spacers along the windshield fence as required.
4. Install a new rubber seal along the sides of the windshield.
5. Using an assistant, position the windshield into the windshield opening and against the windshield fence and spacers.
6. Verify the windshield lays evenly against the fence at the top, bottom and sides of the opening. If not, the fence must be formed to the shape of the windshield.
7. Mark the windshield and the windshield fence with a grease pencil or pieces of masking tape to use as a reference for installation.
8. Using an assistant, remove the windshield from the windshield opening and place it on a suitable padded work surface.

WARNING: **Do not use solvent based glass cleaners to clean the windshield before applying glass prep and primer or poor glass adhesion may result.**

9. Clean the inside of the windshield with an ammonia based glass cleaner and a lint-free cloth.

10. Apply glass prep adhesion promoter 25 mm (1 in.) wide (1) around the perimeter of the windshield (2) and 5 mm (0.2 in.) from the edge of the glass and wipe dry with a clean lint-free cloth until no streaks are visible.

11. Apply glass primer 25 mm (1 in.) wide (1) around the perimeter of the windshield (2) and 5 mm (0.2 in.) from the edge of the glass. Allow at least three minutes drying time.



12. Using a flashlight, verify that the primer is completely and evenly installed along the perimeter of the windshield.

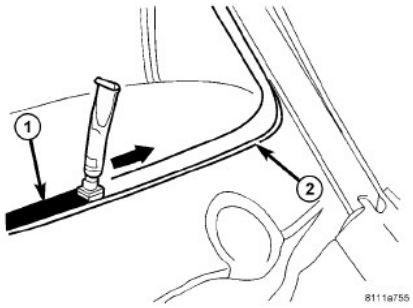
13. Re-prime any area that is not fully and evenly primed.

14. Clean the windshield fence with an ammonia based glass cleaner and a lint-free cloth.

15. Apply pinch weld primer 15 mm (0.75 in.) wide (1) around the windshield fence (2). Allow at least three minutes drying time.

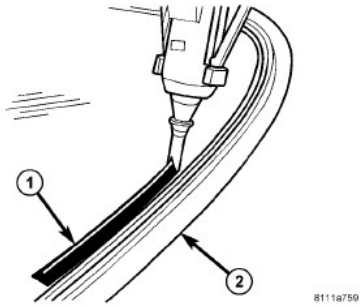
16. Using a flashlight, verify that the primer is completely and evenly installed along the windshield fence.

17. Re-prime any area that is not fully and evenly primed.



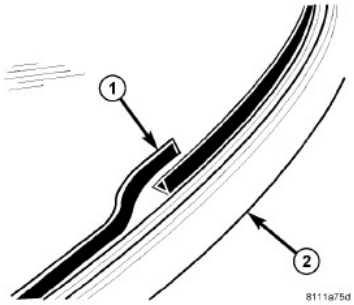
CAUTION: **Always apply the bead of adhesive to the windshield. Always install the windshield within 5 minutes after applying the adhesive.**

NOTE: If the original urethane adhesive has been exposed for more than 12 hours, the entire adhesive area will need to be re-primed prior to installing new adhesive.



18. Apply approximately a 10 mm (0.4 in.) wide bead of adhesive (1) with a triangular nozzle approximately 6 mm (0.230 in.) from the edge of the glass (2) starting at the bottom center of the windshield.

19. Run the end of the adhesive bead (1) on the windshield (2) parallel to the start of the bead and smooth the ends flush.



20. Using an assistant, position the windshield over the windshield opening.

21. Using the grease pencil marks or tape as reference points, align the windshield to the windshield opening.

22. Carefully lower the windshield into the windshield opening. Guide the windshield and the rubber seals on the sides of the windshield into its proper location.

CAUTION: **It is not possible to move the windshield after installation. The windshield should never be pressed into place by more than one person, because the windshield can break if pressed simultaneously on both sides.**

23. Push the windshield inward until the windshield comes into contact with the spacers ocated on each side and the bottom of the windshield fence.

24. Install the cowl grill (Refer to 23 - Body/Exterior/COVER, Cowl Panel - Removal) .

25. Install the rear view mirror onto the windshield (Refer to 23 - Body/Interior/MIRROR, Rearview - Installation) .

2014 Dodge JC - DODGE JOURNEY

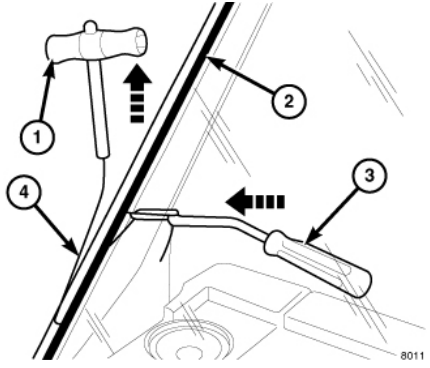
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Before proceeding with the following repair procedure, review all warnings and cautions (Refer to 23 - Body/Stationary Glass - Warning) .
2. Remove the rear view mirror (Refer to 23 - Body/Interior/MIRROR, Rearview - Removal) .
3. Remove the cowl grille (Refer to 23 - Body/Exterior/COVER, Cowl Panel - Removal)



CAUTION: **Be careful not to damage painted surfaces when removing moldings or cutting urethane around the windshield.**

4. Using an assistant and a wire-type windshield cut-out tool (1, 3 and 4), cut and separate the urethane adhesive (2) securing the windshield to the windshield fence.
5. Carefully remove the windshield from the vehicle.
6. Remove molding from the sides of the windshield.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The power window system allows each of the door windows to be raised and lowered electrically by actuating a switch on each door panel. A master switch on the drivers door allows the driver to raise or lower each of the passenger door windows and to lock out the individual switches on the passenger doors from operation. The power window system receives battery feed through a fuse in the Body Control Module (BCM) to the door modules. Their are two door modules, the Driver Door Module (DDM) and the Passenger Door Module (PDM). This is only powered when the ignition switch is in the RUN or ACCESSORY position.

If equipped, the windows have the option of auto up/down. If equipped, the four door gets auto-up/down feature, while the two door just gets the auto-down feature.

The window motors are replaced with the window regulator assembly. If the window motors require replacement, the window regulator must be replaced. For the front door (Refer to 08 - Electrical/8N - Power Systems/Power Windows/MOTOR, Window Regulator - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

Power Window Switch – The power windows are controlled by a window/lock switch on the trim panel of each front door. Switches in the driver door window/lock switch allows the driver to control the passenger windows. The power window switch for the driver side front door window has a second detent position beyond the normal Down position, that provides an automatic one-touch window down feature. Some vehicles may be equipped with an express closing feature (front windows only). During an express closing, anytime an obstacle is detected in the way of the glass, the motor will stop and reverses travel to avoid pinching an occupant fingers. Modules in the doors are programmed to compare the position of the glass to the amount of current being used to drive up the glass. The system also includes various features to manage the perceived forces on the glass as it travels up. If the express closing calibration is lost, the system will self-calibrate itself after the windows are moved up and down two cycles. The power window switches control the battery and ground feeds to the power window motors. All passenger door power window switches receive their battery and ground feeds through the circuitry of the window/lock switch. When the power window lockout switch is in the Lock position, the battery feed for the individual passenger door power window switches is interrupted. Please review the power window switch service information for further operation detail. (Refer to 08 - Electrical/Power Windows/SWITCH, Power Window/Description)

Door Control Modules (DCM) - The (Driver Door Module (DDM) and Passenger Door Module (PDM)) opens or closes the windows when a actuation input signal from the window switch is received. This is only powered when the ignition switch is in the RUN or ACCESSORY position. Power is supplied to the modules through the Power Distribution Center (PDC). For further DCM/DDM/PDM operation, (08 - Electrical/8E - Electronic Control Modules/MODULE, Door/Description)

Power Window Motor – A permanent magnet reversible motor moves the window regulator through an integral gearbox mechanism. A positive and negative battery connection to the two motor terminals will cause the motor to rotate in one direction. Reversing the current through these same two connections will cause the motor to rotate in the opposite direction. Each individual motor is grounded through the master switch. In addition, each power window motor is equipped with an integral self-resetting circuit breaker to protect the motor from overloads. The power window motor and gearbox assembly cannot be adjusted or repaired. If damaged or ineffective, the entire unit must be replaced. (Refer to 08 - Electrical/Power Windows/MOTOR, Window Regulator/Removal)

EXPRESS DOWN WINDOW FEATURE

This feature allows the driver or front passenger to lower the door glass to its full-down position without holding the switch while the glass is in motion. To activate the Expess-down feature depress the window switch to its second detent and release, the door glass will lower automatically. This feature may also be controlled and allows you to remotely lower both front door windows at the same time. To use this feature, press and release the UNLOCK button on the Remote Keyless Entry (RKE) transmitter and then immediately press and hold the UNLOCK button until the windows lower to the desired level or until they lower completely.

EXPRESS AUTO-Up Feature With Anti-Pinch Protection

AUTO-Up Feature With Anti-Pinch Protection — If Equipped Lift the window switch to the second detent, release, and the window will go up automatically. To stop the window from going all the way up during the AUTO-up operation, push down on the switch briefly. To close the window part way, lift the window switch to the first detent and release it when you want the window to stop.

Anti-Pinch Functionality - The Anti-Pinch strategy is only active after the system has been initialized. This function will work during manual and express window functions. If the window runs into any obstacle during auto-closure, it will reverse direction and then go back down. Remove the obstacle and use the window switch again to close the window. Any impact due to rough road conditions may trigger the auto-reverse function unexpectedly during auto-closure. If this happens, pull the switch lightly to the first detent and hold to close the window manually.

2014 Dodge JC - DODGE JOURNEY

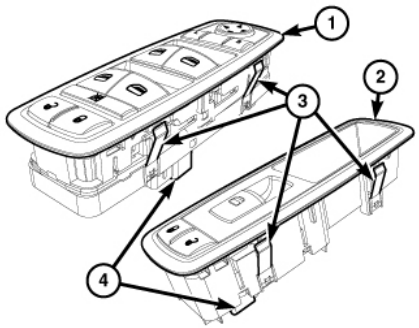
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

A front door power switch module and bezel unit is located near the forward end of the arm rest of each front door trim panel. Two different modules are used: a driver side module (1), and a passenger side module (2). Each switch button in both modules is identified with either an International Control and Display Symbol icon or text that clearly identifies the switch function, and each switch button has a Light Emitting Diode (LED) unit soldered to the switch circuit board that provides back lighting of the icon or text for night visibility.

Each switch module housing is secured within the trim panel armrest by four spring clip retainers (3), two on each side of the switch module housing. The passenger side switch module includes a small cubby bin. A connector receptacle (4) integral to the switch module housing connect the switches to the vehicle electrical system through dedicated take outs and connectors of the door wire harness.

The front door power switch modules include the following switches:



2824067

- **Power Lock Switch** - A momentary switch button to control the **Lock** function of the power lock system.
- **Power Unlock Switch** - A momentary switch button to control the **Unlock** function of the power lock system.
- **Power Mirror Selector Switch (Driver Side Switch Only)** - Three mirror selector switch buttons choose the power mirror to be adjusted, **R** (right), **L** (left) or a power fold position (both mirrors).
- **Power Mirror Direction Control Switch (Driver Side Switch Only)** - After a power mirror is selected, pressing down on one of the arrows on the momentary mirror direction switch will move the selected mirror in that direction for as long as it is held down until the limit of the mirror travel is reached.
- **Power Window Lockout Switch (Driver Side Switch Only)** - A latching push-button power window lockout switch allows the vehicle operator to lock out the power window switches on each front and rear passenger door so that those windows may be operated only from the driver side front door master switches. When the lockout switch is engaged, the LED back lighting for each front and rear passenger door power window switch is extinguished.
- **Power Window Switches** - A single two-way, momentary power window switch with a push-to-open and a lift-to-close tab is provide for each passenger door window while the driver side switch module contains four of these power window switches, one switch dedicated to each door window. The switch tab for the driver side front door power window has a second detent in the down direction which is used to activate the **Auto-Down** (also known as express down or one-touch down) feature. A second detent in the up direction on both front door power window switches activates the **Express-Up** feature.

The front door power switch modules cannot be adjusted or repaired. If damaged or ineffective, the entire driver side or passenger side front door switch module must be replaced as a unit.

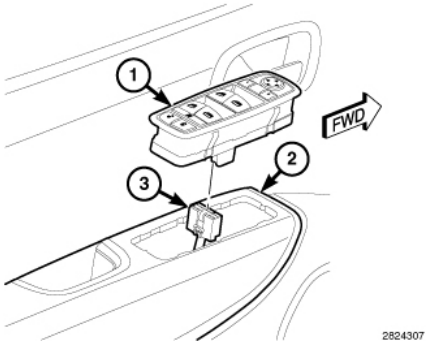
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

FRONT SWITCH MODULE

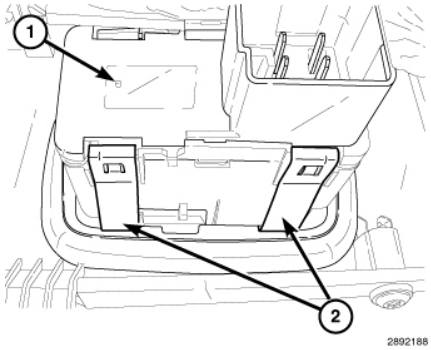
1. Position the front door switch module (1) close enough to the mounting hole in the arm rest (2) of the front door trim panel to access and reconnect the front door wire harness connector (3) to the switch connector receptacle.
2. Align the switch module to the arm rest mounting hole.
3. Using hand pressure, press the switch module firmly and evenly into the mounting hole until the four spring steel retainers of the switch are fully engaged and the switch bezel is fully seated against the arm rest.
4. Connect the battery negative cable.



REAR SWITCH ASSEMBLY

NOTE: Some interior trim packages may make switch removal difficult by traditional means, and require interior trim panel removal to service the switch assembly.

1. Install the switch (1) in the trim panel engaging the four clips (2) that secure the switch.
2. Position the trim panel close enough to the door and connect the electrical connector.
3. Install the rear door interior trim panel, (Refer to 23 - Body/Doors - Rear/PANEL, Rear Door Trim - Installation) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

OPERATION

The driver side front door power switch module combines a power lock switch, a power window switch for each of the four door windows including auto-down (also known as one-touch down or express down) and express up features for both front door windows, a power window lockout switch, a power mirror selector switch, and a power mirror adjustment switch in a single unit. The passenger side power door switch module combines a power lock switch and a passenger side front door power window switch with the auto-down and express up features.

The driver side front door power switch module provides resistor multiplexed outputs to the driver door module indicating the power lock switch selection, hard wired analog outputs indicating the power mirror selector switch and adjustment switch selections, and electronic message outputs over a Local Interface Network (LIN) data bus connection indicating the power window switch selections. The passenger side front door power switch module provides resistor multiplexed outputs to the passenger door module indicating both the power lock and power window switch selections.

The hard-wired circuits between the driver side front door power switch module and the driver side door module or the rear door power window switches may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between the switch module and the door module or in the diagnosis of the electronic controls and communication between other modules and the door module that provide some features of the power lock, power mirror or power window systems. The most reliable, efficient, and accurate means to diagnose the driver side power switch module or the electronic controls and communication related to power lock, power mirror or power window system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

The hard-wired circuits between the passenger side front door power switch module and the passenger side door module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between other modules and the door module that provide some features of the power lock or power window systems. The most reliable, efficient, and accurate means to diagnose the power switch module or the electronic controls and communication related to power lock or power window system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

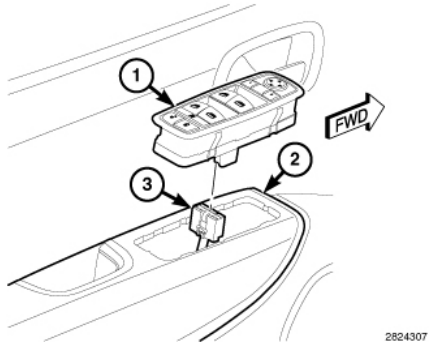
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

FRONT SWITCH MODULE

1. Disconnect and isolate the battery negative cable.
2. Using a trim stick or another suitable wide flat-bladed tool, pry the bezel of the front door switch module (1) up and away from the front door trim panel arm rest (2) far enough to disengage the four spring steel retainers of the switch from the arm rest opening.
3. Pull the switch module away from the mounting hold of the arm rest far enough to access and disconnect the door wire harness connector (3) from the switch connector receptacle.
4. Remove the switch module from the vehicle.



REAR SWITCH ASSEMBLY

NOTE: Some interior trim packages may make switch removal difficult by traditional means, and require interior trim panel removal to service the switch assembly.

1. Remove the rear door interior trim panel, (Refer to 23 - Body/Doors - Rear/PANEL, Rear Door Trim - Removal) .
2. Pull the trim panel away far enough to access and disconnect the electrical connector.
3. Access the four clips (2) that secure the switch (1) to the trim panel from the back. Compress the clips and remove the switch.

DOOR MODULE LEARN PROCEDURES

NOTE:

- This procedure must be performed anytime the power window system has been serviced in either front door or when there is a possible concern with a door module calibration.
- The battery must be fully charged or the vehicle running before proceeding with the learn procedure.
- All doors must be completely closed before proceeding.
- It is suggested to sit inside the vehicle in the drivers seat and close the door.

Express-up / Express-down possible concerns.

- Glass will not lower all the way down flush to the belt-line.
- Glass will not raise fully; wind noise / water leak.
- Glass will not raise automatically (Expess-up) after lifting the switch to the second detent and releasing.

To relearn the door module memory after module replacement, perform the following procedure:

1. Check and repair any door module Diagnostic Trouble Code (DTC)(s) unrelated to missing calibration before proceeding.
2. Using the window switch, lower the door glass to the full-down position by pushing down (depress) the window switch to its second detent and hold the switch until the door glass is fully open. Continue to hold the window switch down for two seconds after the door glass is fully open.
3. Raise the door glass to the full-up position by pulling up on the window switch and hold the switch until the door glass is fully closed. Continue to hold the window switch up for two seconds after the door glass is full closed.
4. Code should now be stored. Clear code and test window operations.

To relearn the door module memory after window/regulator replacement, perform the following procedure:

1. Using the scan tool, go to the network topology screen.
2. Click on the Diagnostic Procedures tab at the lower portion of the screen.
3. Run ECU Reset for DDM/PDM.
4. DDM/PDM calibration missing DTC will now set.
5. Using the window switch, lower the door glass to the full-down position by pushing down (depress) the window switch to its second detent and hold the switch until the door glass is fully open. Continue to hold the window switch down for two seconds after the door glass is fully open.
6. Raise the door glass to the full-up position by pulling up on the window switch and hold the switch until the door glass is fully closed. Continue to hold the window switch up for two seconds after the door glass is full closed.
7. DTC will now be stored. Clear code and test window operations.

DESCRIPTION

Each door has a permanent magnet reversible electric motor with a hall effect sensor. This hall effect sends an alternating signal (open/ground) to the Drivers Door Module (DDM) whenever the window motor is moving.

The hall effect sensor and motor is serviced with the regulator as an assembly (Refer to 23 - Body/Door - Front/REGULATOR, Window - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

A positive and negative battery connection to the two motor terminals will cause the power window motor to rotate in one direction. Reversing the current through these same two connections will cause the motor to rotate in the opposite direction.

Because the Drivers Door Module (DDM) drives the window, it can sense when the top and bottom travel has been reached and stop driving the window regardless of the window switch position (no hall pulses within 50 ms). The DDM considers the Hall Effect faulted if no pulses are sensed when the window is driven up and down. When this condition is detected, the DDM will activate the motor until the switch is released or a stuck fault is set (10 seconds). In addition, each power window motor is equipped with an integral self-resetting circuit breaker to protect the motor from overloads.

The driver side motor is controlled directly by the DDM. The passenger side motor receives current through a window up relay and a window down relay. These are located near the steering column. The up and down window relays are controlled by the DDM.

There is also a 30 Amp fuse in the Power Distribution Center (PDC) to protect the passenger window circuits and a 30 AMP fuse in the PDC to protect the drivers window circuits..

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

An electrically-operated horn system is standard factory-installed equipment in this vehicle. Depressing the Driver AirBag (DAB) trim cover in the center of the steering wheel actuates the horn switch contacts, which provides the vehicle operator with a convenient, audible signaling device that can be used to alert pedestrians or the operators of other vehicles in near proximity.

The Body Control Module (BCM) (also known as the Common Body Controller/CBC) serves as the controller for the horn system, which also allows the BCM to utilize the horn system when providing audible outputs to support other vehicle features such as the horn chirp verification of the Remote Keyless Entry (RKE) and Remote Start systems, as well as the pulsing horn deterrent feature of the optional Vehicle Theft Alarm (VTA) and RKE Panic mode.

The horn system includes the following major components, which are described in further detail elsewhere in this service information:

- **Horn Relay** - The horn relay is soldered onto the Printed Circuit Board (PCB) located within the Power Distribution Center (PDC) and is not serviceable. The PDC is located in the left front corner of the engine compartment near the battery.
- **Horns** - The standard dual-note horns are located on a bracket secured to the Front End Module (FEM) carrier just to the right of center of the upper radiator cross member, just behind the radiator grille panel. The appearance shield and radiator grille panel must be removed to gain access to the horns for service.
- **Horn Switch Plate** - The floating horn switch plate is secured to the back of the DAB module within the steering wheel hub cavity and also serves as the mounting bracket between the DAB and the steering wheel.

Certain functions and features of the horn system rely upon resources shared with other electronic modules in the vehicle over the Controller Area Network (CAN) data bus. Other electronic modules in the vehicle that may affect horn system operation are:

- **Body Control Module** - The Body Control Module (BCM) is located on the right cowl side inner (kick) panel within the passenger compartment, where it is concealed behind the cowl side inner trim and the instrument panel. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Body Control/Description) .
- **Radio Frequency Hub Module** - The Radio Frequency Hub Module (RFHM) (also known as the RF Hub) is located on the upper liftgate opening reinforcement at the rear of the passenger compartment where it is concealed above the headliner trim. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Radio Frequency (RF Hub) /Description).

The BCM and the RFHM each contain a microcontroller and programming that allow them to communicate with each other and other electronic modules in the vehicle using the Controller Area Network (CAN) data bus. (Refer to 08 - Electrical/8E - Electronic Control Modules/COMMUNICATION/Description) .

Hard wired circuitry connects the various horn system components to each other through the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other and to the vehicle electrical system through the use of a combination of soldered splices, splice block connectors and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention as well as pin out and location views for the various wire harness connectors, splices and grounds.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Dual electromagnetic diaphragm-type horns are standard equipment on this vehicle. A low note (2) and a high note (1) trumpet-style horn are each secured to a mounting bracket (3). The horn and mounting bracket unit is then secured by a single screw to the forward-facing surface of the upper radiator cross member of the Front End Module (FEM). Internally the two horns are identical in construction and the external horn trumpets are symmetrically opposite.

A short jumper harness connects the horns to each other electrically so they can both be connected through a single connection (4) integral to the right horn. A dedicated take out and connector of the headlamp and dash wire harness connects the horns to the vehicle electrical system.

The two horns and the mounting bracket are factory-tuned as a unit and, therefore, are serviced only as a unit. These horns cannot be adjusted or repaired. If either horn or the mounting bracket is ineffective or damaged, the entire unit must be replaced.

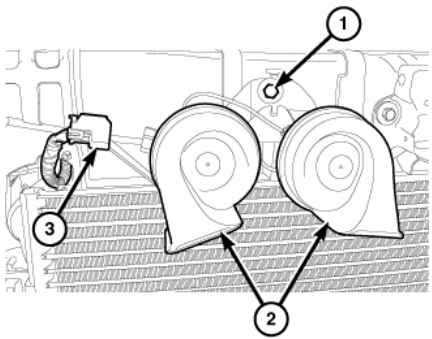
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Pull the top of the radiator grille of the front fascia away from the upper radiator cross member far enough to position the horns and mounting bracket unit (2) to the forward facing surface of the upper radiator cross member of the Front End Module (FEM).
2. Pull the top of the radiator grille of the front fascia away from the upper radiator cross member far enough to install and tighten the screw (1) that secures the horn mounting bracket to the forward facing surface of the upper radiator cross member. Tighten the screw securely.
3. Pull the top of the radiator grille of the front fascia away from the upper radiator cross member far enough to access and reconnect the headlamp and dash wire harness connector (3) to the connector for the horns.



4. Reinstall the plastic push pin fasteners that secure the top of the radiator grille of the front fascia to the upper radiator cross member of the Front End Module (FEM). (Refer to 13 - Frame and Bumpers/Bumpers/FASCIA, Front/Installation) .
5. Reconnect the negative cable to the battery.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

Each horn has a path to ground at all times through its wire harness connection to an eyelet terminal secured to the body sheet metal. The horns are completely controlled by a fused B(+) output received through a relay soldered onto the Printed Circuit Board (PCB) within the Power Distribution Center (PDC) and controlled by the Body Control Module (BCM) (also known as the Common Body Controller/CBC).

Within the two halves of the horn housing are a flexible diaphragm, a plunger, an electromagnetic coil and a set of contact points. The diaphragm is secured in suspension around its perimeter by the mating surfaces of the horn housing. The plunger is secured to the center of the diaphragm and extends into the center of the electromagnetic coil. The contact points control the current flow through the windings of the electromagnetic coil.

When the horn is energized, electrical current flows through the closed contact points to the electromagnetic coil. The resulting electromagnetic field draws the plunger and diaphragm toward it until that movement mechanically opens the contact points. When the contact points open, the electromagnetic field collapses allowing the plunger and diaphragm to return to their relaxed positions and closing the contact points again. This cycle continues repeating at a very rapid rate producing the vibration and movement of air that creates the sound that is directed through the horn trumpet outlet.

The horns as well as the hard wired input circuits for the horns may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The horn relay is a electromechanical device that consists of an electromagnetic coil, a resistor and a pair of normally open electrical contacts. One of the two electrical contacts is fixed, while the other contact is movable. The movable relay contact is held away from the fixed contact by spring pressure. The horn relay for this vehicle is soldered in place on the Printed Circuit Board (PCB) internal to the Power Distribution Center (PDC), which is located within the engine compartment near the battery.

The horn relay cannot be repaired or adjusted and, if ineffective or damaged, the entire PDC unit must be replaced.

Labor Operations: Click to display a list of Labor Operations associated with this procedure

The horn relay used in this vehicle is soldered onto a Printed Circuit Board (PCB) internal to the Power Distribution Center (PDC) located in the engine compartment near the battery. The horn relay is integral to and serviced only as a unit with the PDC.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The horn relay within the Power Distribution Center (PDC) switches battery current to the horns when the Body Control Module (BCM) (also known as the Common Body Controller/CBC) energizes the electromagnetic coil of the relay using a High Side Driver (HSD). When the electromagnetic relay coil is energized, it draws and holds the normally open movable contact of the relay against the fixed relay contact. The closed relay contacts supply fused battery current from the PDC to energize the horns.

When the BCM de-energizes the electromagnetic relay coil, spring pressure returns the movable contact to the normally open position, which de-energizes the horns. The resistor within the relay is connected in parallel with the electromagnetic coil, and helps to dissipate voltage spikes that are produced when the coil is de-energized.

The hard wired inputs and outputs of the horn relay in the PDC and the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the BCM or the electronic controls and communication between modules and other devices that provide some features of the BCM controlled horn relay. The most reliable, efficient and accurate means to diagnose the BCM or the electronic controls and communication related to BCM controlled horn relay operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

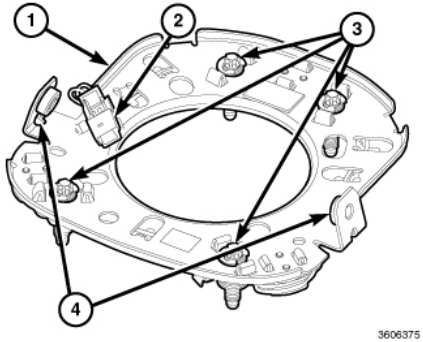
DESCRIPTION

A normally open floating-type horn switch and mounting plate (1) is secured to the back of the Driver AirBag (DAB) housing within the hub cavity of the steering wheel. The four sets of switch electrical contacts are each held open by a coiled spring and captured by a mounting screw (3) and E-clips arranged around the perimeter of the mounting plate. A switch wire harness joins the contacts in a parallel circuit to a connector (2) that is connected to the vehicle electrical system through a dedicated take out and connector of the steering wheel wire harness.

The stamped metal switch mounting plate has a mounting tab with a threaded insert (4) on each side, which is used to secure the DAB and floating horn switch assembly within the steering wheel hub cavity with a screw installed through each side of the steering wheel armature. The floating horn switch contacts, mounting plate and wire harness are serviced as a unit. If the horn switch is ineffective or damaged, the entire floating horn switch assembly must be replaced.



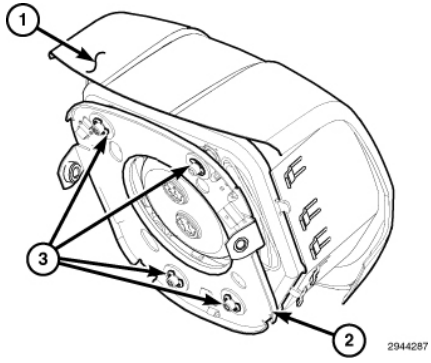
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**



1. Position the floating horn switch and mounting plate unit (2) to the Driver AirBag (DAB) housing (1).
2. Install and tighten the four captive screws (3) that secure the switch and mounting plate to the DAB housing. Tighten the screws securely.
3. Position the DAB and floating horn switch unit close enough to the steering wheel to reconnect the electrical connections at the back of the airbag housing.
4. Reconnect the steering wheel wire harness connector to the floating horn switch connector on the back of the switch.
5. Reconnect the wire connectors to the airbag inflator connector receptacles by pressing straight in on the connector insulator. Be certain to engage each keyed and color-coded connector to the matching connector receptacle. You can be certain that each connector is fully engaged in its receptacle by listening carefully for a distinct, audible click as the connector latches snap into place.
6. Push each of the Connector Position Assurance (CPA) locks firmly into the DAB connector insulator until it is flush with the upper surface of the insulator.
7. Reinstall the DAB into the steering wheel. (Refer to 10 - Restraints/AIR BAG, Driver - Installation) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

When the Driver AirBag (DAB) trim cover in the center of the steering wheel is depressed, the springs between the electrically conductive horn switch contacts are compressed allowing them to contact each other, closing the switch circuit. When the DAB trim cover is released, the springs between the switch contacts expand, opening the switch circuit.

When any one of the four sets of horn switch contacts forms a completed circuit, a horn request signal is provided to the Local Interface Network (LIN) slave node integral to the speed control switch pod in the right horizontal spoke of the steering wheel. The LIN slave node sends an electronic **horn switch status** message to the LIN master node and Controller Area Network (CAN) data bus gateway integral to the Steering Angle Sensor (SAS) on the clockspring. The SAS then relays an electronic **horn request** message to the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the CAN data bus, and the BCM activates a high side driver to energize the horn relay.

The horn switch as well as the hard wired output circuits for the horn switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

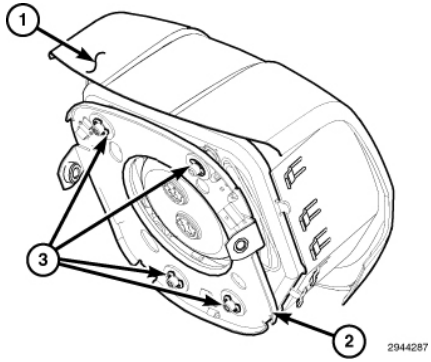
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Remove the Driver AirBag (DAB) (1) and floating horn switch (2) from the steering wheel as a unit. (Refer to 10 - Restraints/AIR BAG, Driver - Removal) .
2. Pull the DAB and floating horn switch unit away from the steering wheel far enough to access the electrical connections at the back of the unit.
3. Disconnect the steering wheel wire harness connector from the floating horn switch connector on the back of the switch.



CAUTION: **Do not pull on the clockspring pigtail wires or pry on the connector insulators to disengage them from the Driver AirBag (DAB) inflator initiator connector receptacles. Improper removal of these pigtail wires and their connector insulators can result in damage to the airbag circuits or the connector insulators.**

4. The clockspring DAB pigtail wire connector insulators are secured by integral latches and a Connector Position Assurance (CPA) lock to the airbag inflator connector receptacles, which are located on the back of the DAB housing. Pull the lock straight out from the connector insulator, then pull the insulators straight out from the airbag inflator to disengage the latches and disconnect them from the connector receptacles.
5. Fully loosen each of the four captive screws (3) that secure the floating horn switch unit to the airbag housing.
6. Remove the switch and mounting plate as a unit from the airbag housing.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The horn system components operate on battery current received through non-switched fused B(+) circuits so that the system will remain operational, regardless of the status of the ignition switch (also known as the Keyless Ignition Node/KIN). The Body Control Module (BCM) controls the output of battery current to the horns through a horn relay soldered to a Printed Circuit Board (PCB) located within the Power Distribution Center (PDC). The BCM controls the relay based upon internal programming, hard wired inputs from the horn switch as well as electronic message inputs received from the Radio Frequency Hub Module (RFHM) (also known as the RF Hub) over the Controller Area Network (CAN) data bus.

The vehicle operator can control typical horn system signaling through the horn switch within the hub of the steering wheel. When the Driver AirBag (DAB) trim cover is depressed, it provides a hard wired analog input to the Local Interface Network (LIN) slave node integral to the speed control switch pod. The LIN slave node then sends electronic **horn switch status** messages to the LIN master node integral to the Steering Angle Sensor (SAS) (also known as the Steering Control Module. The SAS is also a gateway to the CAN data bus, and relays an electronic **horn request** message to the BCM over the CAN data bus.

In addition, the RFHM sends electronic **horn request** messages to the BCM over the CAN data bus in response to inputs received from the FOB with Integrated Key (FOBIK) Remote Keyless Entry (RKE) transmitter in vehicles with the PEKG system. Lastly, as the Vehicle Theft Security System (VTSS) controller, the BCM can activate the horn system based upon programming and both hard wired and electronic message inputs from the various VTSS components.

The horns can be activated by the BCM to support each of the following features:

- **Remote Keyless Entry System** - Remote Keyless Entry (RKE) system **Lock** request audible verification.
- **Remote Keyless Entry System** - Remote Keyless Entry (RKE) system **Panic** mode audible alert.
- **Remote Start System** - Remote Start System **Start** request audible verification.
- **Vehicle Theft Alarm** - Vehicle Theft Alarm (VTA) audible alarm.

The RKE system **Lock** request audible verification is a customer programmable feature, which allows the feature to be enabled or disabled to suit individual preferences. (Refer to 08 - Electrical/8M - Message Center/CENTER, Electronic Vehicle Information/Operation) .

The hard wired circuits between components related to the horn system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the horn system or the electronic controls and communication between modules and other devices that provide some features of the horn system. The most reliable, efficient and accurate means to diagnose the horn system or the electronic controls and communication related to horn system operation requires the use of a diagnostic scan tool.

2014 Dodge JC - DODGE JOURNEY

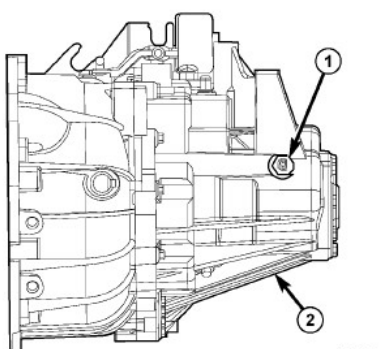
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Vehicles equipped with a manual transmission (2) have a normally open, spring-loaded plunger type backup lamp switch (1). Vehicles with an optional electronic automatic transmission have a Transmission Range Sensor (TRS) that is used to perform several functions, including that of the backup lamp switch. The TRS is described in further detail elsewhere in this service information. Refer to the service and diagnostic information for the automatic transmission type installed in the vehicle.

The backup lamp switch is located in a threaded hole on the left facing surface of the manual transmission housing. The switch has a threaded body and a hex formation near the plunger end of the switch. An integral connector receptacle at the end of the switch opposite the plunger connects the switch to the vehicle electrical system through a take out and connector of the engine wire harness. When installed, only the switch connector and the hex formation are visible on the outside of the transmission housing.

The backup lamp switch cannot be adjusted or repaired and, if ineffective or damaged, the entire switch unit must be replaced. Refer to the service and diagnostic information for the manual transmission type installed in the vehicle.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The backup lamp switch controls a path to ground for the Body Control Module (BCM) (also known as the Common Body Controller/CBC) on the reverse switch signal circuit. The BCM reads this input through an internal pull-up, then controls an output through a high side driver that regulates the flow of battery voltage to the backup lamp bulbs as appropriate on the backup lamp feed circuit. The switch plunger is mechanically actuated by the gearshift mechanism within the transmission, which will depress the switch plunger and close the switch contacts whenever the REVERSE gear has been selected. The switch receives ground at all times through a take out and eyelet terminal of the wire harness that is secured to the body sheet metal.

The backup lamp switch as well as the hard wired inputs and outputs of the switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between other modules and devices that rely upon inputs from the backup lamp switch. The most reliable, efficient, and accurate means to diagnose the electronic controls and communication related to backup lamp switch operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

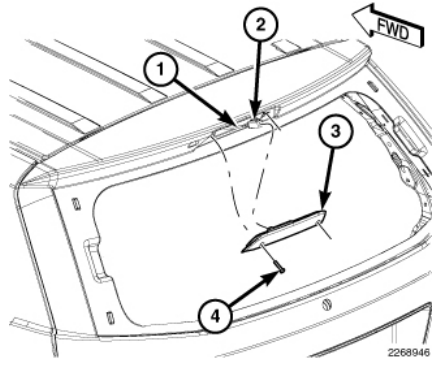
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure



1. Check to be certain that the two U-nuts in the Center High Mounted Stop Lamp (CHMSL) opening of the liftgate header panel are properly installed and in good condition.
2. Position the CHMSL (3) near the opening in the liftgate header panel.
3. Reconnect the connector (2) of the liftgate wire harness (1) to the connector receptacle on the back of the lamp.
4. Position the CHMSL into the liftgate header opening.
5. Install and tighten the two screws (4) that secure the CHMSL to the liftgate header panel. Tighten the screws to 1.5 N·m (15 in. lbs.).
6. Reconnect the battery negative cable.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Disconnect and isolate the battery negative cable.
2. Remove the two screws (4) that secure the Center High Mounted Stop Lamp (CHMSL) (3) to the liftgate header panel (1).
3. Pull the CHMSL away from the liftgate far enough to access and disconnect the connector (2) of the liftgate wire harness (1) from the connector receptacle on the back of the lamp.
4. Remove the CHMSL from the liftgate.

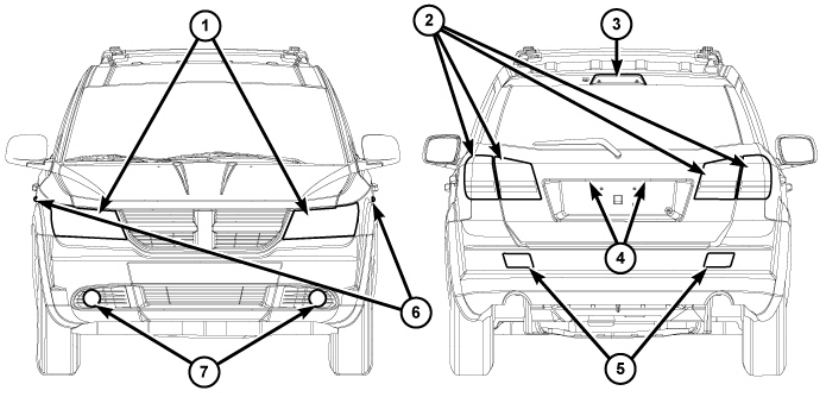
DESCRIPTION



2245903

The exterior lighting system for this vehicle includes the following exterior lamp units:

- **Center High Mounted Stop Lamp (3)** - A standard equipment Center High Mounted Stop Lamp (CHMSL) is centered on the upper liftgate header above the liftgate glass opening at the rear of the vehicle.
- **Front Fog Lamps (7)** - Vehicles equipped with this option have a separate front fog lamp unit mounted near each outboard end of the front fascia, below each front lamp unit.
- **Front Lamp Units (1)** - A standard equipment front lamp unit with two, single-filament headlamp bulbs is located at each outboard side of the grille opening in the Front End Module (FEM).
- **Front Position Lamps** - A front position lamp is integral to each front lamp unit on vehicles manufactured for export markets where they are required.
- **License Plate Lamps (4)** - Two standard equipment rear license plate lamp units are integral to the liftgate handle assembly, just above the license plate tub formation on the outer liftgate panel.
- **Rear Fog Lamps (5)** - A rear fog lamp unit is mounted near each outboard end of the rear fascia, below each rear lamp unit on vehicles manufactured for export markets where they are required.
- **Rear Lamp Units (2)** - A standard equipment two-piece rear lamp unit is mounted on each side at the rear of the vehicle. One piece of the rear lamp is secured to the end of each quarter panel on either side of the liftgate opening and the second piece is secured to each side of the liftgate outer panel, adjacent to the first piece of the rear lamp when the liftgate is closed.
- **Repeater Lamps (6)** - A repeater lamp is mounted to each front fender just behind the front wheel opening on vehicles manufactured for export markets where they are required.

These exterior lighting lamp units and their controls are combined to provide the following exterior lighting features:

- **Automatic Headlamps** - Vehicles with the automatic headlamps option are equipped with a unique headlamp switch that includes an **AUTO** (Automatic) position and have an automatic headlamp sensor to sense ambient light levels. The automatic headlamp sensor is integral to the sun load sensor located on the top of the instrument panel. (Refer to 24 - Heating and Air Conditioning/Controls/SENSOR, Sun - Description) .
- **Backup Lamps** - The backup (or reverse) lamps include a clear bulb, reflector and clear lens that are integral to the liftgate portions of each rear lamp unit.
- **Brake Lamps** - The brake (or stop) lamps include either a clear bulb or multiple Light-Emitting Diode (LED) units, a reflector and a red lens that are integral to the quarter panel portions of each rear lamp unit, and the red lens and multiple LED units of the CHMSL.
- **Daytime Running Lamps** - Daytime Running Lamps (DRL) are standard equipment on vehicles manufactured for sale in Canada and optional on vehicles manufactured for the United States. Vehicles with the DRL feature enabled illuminate the high beam headlamp bulb in each front lamp unit at a reduced intensity to serve as the DRL.
- **Exterior Lamp Fail-Safe Operation** - The Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and the Body Control Module (BCM) (also known as the Common Body Controller/CBC) provide a fail-safe feature which will automatically turn ON the low beam headlamps and all park lamps when the ignition switch is in the ON position and there is no detected input from either the headlamp switch or the multi-function switch, no communication from the Steering Control Module (SCM) or Steering Angle Sensor (SAS) or when either the Local Interface Network (LIN) data bus or the Controller Area Network (CAN) data bus are inoperative.

- **Exterior Lamp Load Shedding** - The Body Control Module (BCM) (also known as the Common Body Controller/CBC) provides a battery saver feature which will automatically turn OFF all exterior lamps (except the park/tail lamps in certain export markets) that remain ON with the ignition switch in the LOCK position after a timed interval of about eight minutes.
- **Front Fog Lamps** - The optional front fog lamps include the clear bulb, reflector and clear lens of each adjustable front fog lamp unit.
- **Hazard Warning Lamps** - The hazard warning lamps include the bulbs, reflectors and lenses of each lamp in the right and left, front and rear turn signal circuits.
- **Headlamps** - The headlamps include dual, single filament halogen bulbs, an adjustable reflector and a clear lens integral to each front lamp unit.
- **Headlamp Leveling** - Headlamp leveling is available only in certain markets where it is required equipment. A headlamp leveling actuator motor on each headlamp unit and a headlamp leveling switch integral to the dimmer module in the instrument panel headlamp switch bezel allows the headlamp beam pattern to be adjusted by the vehicle operator from the interior of the vehicle to compensate for passenger or cargo loads.
- **Headlamp Time Delay** - On vehicles equipped with the automatic headlamps option, when this feature is enabled the low or high beam headlamps remain illuminated for a programmable delay interval of 0 (disabled), 30, 60 or 90 seconds after the ignition switch has been turned to the OFF position. This feature is customer programmable using the Electronic Vehicle Information Center (EVIC) switches and the U-Connect Touch™ screen module in the Integrated Center Stack (ICS).
- **Headlamps With Wipers** - Vehicles with the automatic headlamps option have an automatic headlamps-with-wipers feature. When this feature is enabled and the **AUTO** position of the headlamp switch is selected, the headlamps are turned ON automatically whenever the windshield wipers are turned ON; and, if the headlamps were turned ON automatically when the wipers were turned ON, they will also turn OFF automatically when the wipers are turned OFF if the appropriate ambient light conditions exist. This feature is customer programmable using the Electronic Vehicle Information Center (EVIC) switches and the U-Connect Touch™ screen module in the Integrated Center Stack (ICS).
- **Optical Horn** - Also known as flash-to-pass, the beam selection function of the multi-function switch control stalk has a momentary intermediate position that allows the headlamp high beams to be flashed momentarily, without changing the headlamp beam selection.
- **Park/Tail Lamps** - The front park lamps include the amber bulbs, reflectors and clear lenses integral to each front lamp unit and, if the vehicle is so equipped, the clear position lamp bulb integral to each front lamp unit. The rear tail lamps include either the clear bulb or the multiple LED units, a reflector and a red lens integral to both the quarter panel and liftgate portions of each rear lamp unit as well as the bulbs and lenses of the license plate lamp units.
- **Rear Fog Lamps** - Rear fog lamps are available only in certain export markets where they are required equipment. The rear fog lamps include a clear bulb, a red lens and a reflector that are integral to each rear fog lamp unit.
- **Turn Signal Lamps** - The front turn signal lamps include an amber bulb, a reflector and a clear lens that are integral to each front lamp unit. In certain export markets where they are required, the clear bulbs and lenses of the repeater lamps on each front fender will also be included in the front turn signal circuits. The rear turn signal lamps include an amber bulb, a reflector and a clear lens that are integral to the quarter panel portion of each rear lamp unit.

Other components of the exterior lighting system for this vehicle include:

- **Backup Lamp Switch** - A plunger-type backup lamp switch is installed through the transmission housing of vehicles equipped with a manual transmission and is actuated by the shifter mechanism within the transmission when REVERSE gear is selected. On vehicles with an optional automatic transmission, a stand alone Transmission Range Sensor (TRS) performs the backup lamp switch function.
- **Body Control Module** - The Body Control Module (BCM) (also known as the Common Body Controller/CBC) is located beneath the instrument panel on the passenger side of the vehicle. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Body Control - Description) .
- **Brake Lamp Switch** - A lever-actuated brake pedal position sensor serves as the brake lamp switch in this vehicle. The brake pedal position sensor is located on the brake pedal support bracket under the instrument panel and is actuated by a pin on the brake pedal arm when the brake pedal is depressed.
- **Controller Antilock Brake** - A Controller Antilock Brake (CAB) (also known as the Antilock Brake Module/ABM) is located in the engine compartment below the brake master cylinder. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Anti-Lock Brake System - Description) .
- **Hazard Switch** - A latching push button-actuated hazard switch is integral to the instrument panel switch bank in the lower vehicle feature controls module (also known as the Integrated Center Stack/ICS) located in the center stack area of the instrument panel.
- **Headlamp Leveling Switch** - A four position thumbwheel-actuated headlamp leveling switch is integral to the dimmer module located in the headlamp switch bezel of the instrument panel in vehicles manufactured for certain export markets where the headlamp leveling feature is required.
- **Headlamp Switch** - A rotary knob-actuated headlamp switch is located in the headlamp switch bezel of the instrument panel. The headlamp switch is used to select the park lamps, headlamps or fog lamps.
- **Instrument Cluster** - The Instrument Cluster (IC) is also known as the Common Instrument Cluster (CIC) in this vehicle. The IC is located in the instrument panel above the steering column opening, directly in front of the driver. (Refer to 08 - Electrical/8J - Instrument Cluster - Description) .
- **Instrument Panel Switch Bank** - The instrument panel switch bank contains the hazard switch. The switch bank is located in the lower vehicle feature controls module (also known as the Integrated Center Stack/ICS) located in the center stack area of the instrument panel. (Refer to 08 - Electrical/8J - Instrument Cluster/POD, Switch Bank - Description) .
- **Multi-Function Switch** - The multi-function switch is located on the steering column, just below the steering wheel. A control stalk that extends from the left side of the switch is used to select the turn signal lamps (right or left) and to select the headlamp beam (low, high or optical horn).
- **Park Brake Switch** - A park brake switch is located on the park brake mechanism. On vehicles with a manual transmission, a park brake hand lever mechanism is located on the side of the floor panel transmission tunnel between the two front seats. On vehicles with an automatic transmission, a park brake foot lever mechanism is located on the driver side cowl side inner panel below the instrument panel.
- **Steering Angle Sensor** - The Steering Angle Sensor (SAS) is integral to the clockspring. The SAS is a Local Interface Network (LIN) master node and a gateway to the Controller Area Network (CAN) data bus. (Refer to 05 - Brakes/Electrical/SENSOR, Steering Wheel Angle - Description) .
- **Steering Control Module** - The Steering Control Module (SCM) is located within the multi-function switch housing on the top of the steering column, just below the steering wheel. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Steering Column - Description) .
- **Trailer Tow Wiring** - Vehicles equipped with an optional Trailer Tow Prep package include a wire harness, three relays, a conventional 4-way light duty trailer tow connector and an installation instruction sheet shipped loose in the glove box from the factory for installation by the vehicle owner or the dealer.
- **Turn Signal Cancel Cam** - The turn signal cancel cam is integral to the clockspring. The turn signal cancel cam provides automatic turn signal cancellation as the steering wheel is rotated back to its centered position following a vehicle turning maneuver.

Hard wired circuitry connects the exterior lighting system components to the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system and to the exterior lighting components through the use of a combination of soldered splices, splice block connectors and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

BULBS

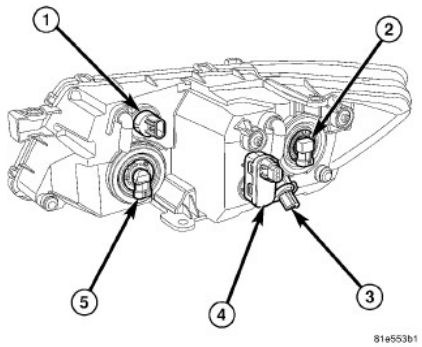
Labor Operations: Click to display a list of Labor Operations associated with this procedure

HEADLAMP HIGH BEAM

CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**

CAUTION: **Do not contaminate the bulb glass by touching it with your fingers or by allowing it to contact other oily surfaces. Shortened bulb life will result.**

1. Align the headlamp bulb and base (5) with the keyed opening on the back of the front lamp unit reflector.
2. Insert the bulb into the reflector until the base is firmly seated.
3. Rotate the bulb base clockwise about 30 degrees to lock it into place.
4. Reconnect the wire harness connector to the connector receptacle integral to the headlamp bulb base.
5. Reconnect the battery negative cable.



HEADLAMP LOW BEAM

CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**

CAUTION: **Do not contaminate the bulb glass by touching it with your fingers or by allowing it to contact other oily surfaces. Shortened bulb life will result.**

1. Align the headlamp bulb and base (2) with the keyed opening on the back of the front lamp unit reflector.
2. Insert the bulb into the reflector until the base is firmly seated.
3. Rotate the bulb base clockwise about 30 degrees to lock it into place.
4. Reconnect the wire harness connector to the connector receptacle integral to the headlamp bulb base.
5. Reconnect the battery negative cable.

POSITION LAMP

CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**

NOTE: The following procedure applies only to vehicles manufactured for certain export markets. Vehicles manufactured for domestic markets do not have a position lamp bulb, socket or wiring provided in the front lamp unit.

1. Align the base of the bulb with the position lamp bulb socket (3).
2. Push the bulb straight into the socket until the base is firmly seated.
3. Align the socket and bulb with the keyed opening on the back of the front lamp unit housing.
4. Insert the socket and bulb straight into the housing until the socket is firmly seated.
5. Rotate the socket clockwise about 30 degrees to lock it into place.
6. Reconnect the wire harness connector to the connector receptacle integral to the position lamp bulb socket.
7. Reconnect the battery negative cable.

TURN SIGNAL/SIDE MARKER LAMP

CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**

1. Align the base of the bulb with the park/turn signal lamp bulb socket (1).
2. Push the bulb straight into the socket until the base is firmly seated.
3. Align the socket and bulb with the keyed opening on the back of the front lamp unit housing.
4. Insert the socket and bulb straight into the housing until the socket is firmly seated.
5. Rotate the socket clockwise about 30 degrees to lock it into place.
6. Reconnect the wire harness connector to the connector receptacle integral to the park/turn signal lamp bulb socket.
7. Reconnect the battery negative cable.

STANDARD PROCEDURE - LAMP LENS FOGGING

Some customers may report that on occasion, vehicle exterior lamp assemblies are fogged with a light layer of condensation on the inside of the lenses. This may be reported after the lamps have been turned on and brought up to operating temperature, turned off, and then rapidly cooled by cold water (such as rain, or the water from a car wash). Lens fogging can also occur under certain atmospheric conditions after a vehicle has been parked outside overnight (i.e., a warm humid day followed by clear cool night). This will usually clear as atmospheric conditions change to allow the condensation to change back into a vapor. Turning the lamps on will usually accelerate this process.

A lamp that exhibits condensation/fogging should be evaluated in a service bay environment by first drying all water from the outside surface of the lens and operating the lamp for 20 minutes. If the condensation/fogging has begun to clear from the lamp lens after 20 minutes with the lamps operating, this indicates the lamp sealing has not been breached, and the lamp does not need to be replaced.

If the condensation/fogging has not begun to clear after 20 minutes with the lamps operating, or the lamp has large amounts of water droplets visible on most internal surfaces, this indicates a problem with the lamp sealing that has allowed water to enter the lamp. In this instance, the customer is also likely to report that moisture in the lamp is always present and never disappears. A lamp that exhibits internal moisture permanently should be replaced.

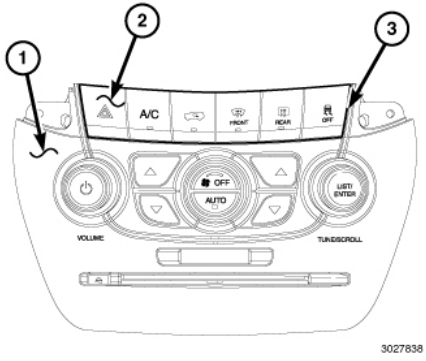
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The hazard switch (2) is integral to the instrument panel switch bank (3) in the vehicle feature controls module (1) (also known as the Integrated Center Stack/ICS), which is secured to the lower instrument panel center stack just below the U-Connect Touch™ screen module. A red, stencil-like International Control and Display Symbol icon for **Hazard Warning** identifies the hazard switch button. The remainder of the hazard switch circuitry is concealed within the instrument panel switch bank.

The hazard switch button has panel lamps dimmer controlled illumination for night visibility. The switch button latches to a slightly lowered position when the hazard warning system is activated and unlatches to a position flush with the other push buttons in the switch bank when the hazard warning is deactivated.



All of the circuitry and components of the hazard switch are contained within the molded plastic vehicle feature controls module. A single connector receptacle is integral to the back of the module. The switch is connected to the vehicle electrical system through a dedicated take out and connector of the instrument panel wire harness.

The hazard switch cannot be adjusted or repaired and, if ineffective or damaged, the entire instrument panel switch bank and vehicle features control module unit must be replaced. (Refer to 08 - Electrical/8J - Instrument Cluster/POD, Switch Bank - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The status of the hazard switch is continually monitored by the circuitry within the instrument panel switch bank in the vehicle features control module (also known as the Integrated Center Stack/ICS). The switch receives battery voltage at all times through a fused battery feed circuit, and a path to ground at all times through the instrument panel wire harness.

Whenever the hazard switch is in its latched and lowered position, the hazard warning system is selected and the switch bank circuitry provides a hard wired output to the Body Control Module (BCM) (also known as the Common Body Controller/CBC). When the BCM receives a hazard switch input, it then controls hazard warning system operation and flash rate by controlling battery voltage outputs through high side drivers on the right and left, front and rear turn signal feed circuits.

The BCM also sends the appropriate electronic messages to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) over the Controller Area Network (CAN) data bus to control the illumination and flash rate of the right and left turn signal indicators, as well as to control the click rate of an electromechanical relay soldered onto the IC electronic circuit board that emulates the sound emitted by a conventional hazard warning flasher.

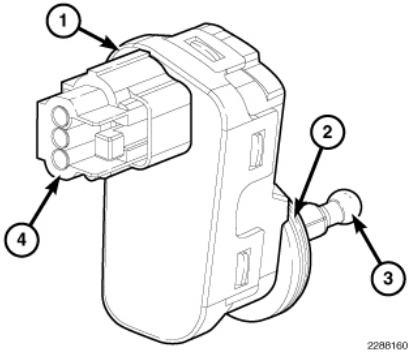
The hard wired circuits for the instrument panel switch bank may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the hazard warning switch or the electronic controls and communication between other modules and devices that provide some features of the hazard warning system. The most reliable, efficient, and accurate means to diagnose the hazard switch or the electronic controls and communication related to hazard warning system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The headlamp leveling motor (1) is located on the rear surface of each front lamp unit on vehicles equipped with the headlamp leveling system, which is available only in certain export markets where it is required equipment. The motor is encased within a molded plastic housing and is secured by an integral wedge-type mounting flange (2) to a keyed flange on the back of the front lamp unit housing. A rubber seal around the circumference of the mounting boss seals the motor to the lamp housing.



The outside of the motor housing features an integral molded connector (4) on its upper rearward surface and a plastic pushrod with a ball formation (3) on its free end extends from the motor mounting flange. Within the motor housing is a 12-volt Direct Current (DC) servo motor, an electronic controller board that includes the motor logic circuits, and an integral screw-drive transmission. The headlamp leveling motor is connected to the vehicle electrical system through a dedicated take out and connector of the headlamp and dash wire harness.

The headlamp leveling motor cannot be repaired and, if ineffective or damaged, the entire motor unit must be replaced.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The controller board and logic circuitry of the headlamp leveling motor controls motor operation based upon a voltage signal input received from the Body Control Module (BCM) (also known as the Common Body Controller/CBC). The BCM uses a hard wired input received from the headlamp leveling switch integral to the dimmer module on the instrument panel to determine the correct voltage signal to provide the leveling motor.

The headlamp leveling motors have a path to ground at all times. The motors operate on battery voltage received through the headlamp low beam feed circuits so that the system will only operate when the headlamp low beams are turned ON. When the motor is energized it will extend or retract the motor pushrod through an integral screw-drive transmission. The ball on the end of the pushrod is snapped into a saddle bracket on the back of the reflector within the front lamp unit housing, which will cause the reflector to move as the pushrod is extended or retracted, changing the angle at which the light is projected from the headlamp bulb filaments.

The hard wired circuits for the headlamp leveling motors may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the active electronic elements within the headlamp leveling motors or the electronic controls and communication between other modules and devices that provide some features of the headlamp leveling system. The most reliable, efficient, and accurate means to diagnose the headlamp leveling motor or the electronic controls and communication related to headlamp leveling system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

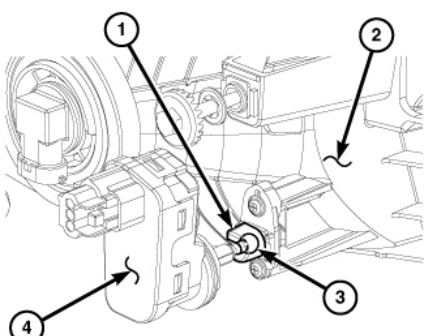
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: The graphic shows the right side front lamp unit as viewed from the back of the lamp with the housing removed. However, the housing cannot be removed from the lamp for service. This view was necessary in order to clearly illustrate the internal engagement of the headlamp leveling motor pushrod with the saddle bracket on the lamp reflector.



2288363

1. Disconnect and isolate the battery negative cable.
2. Remove front lamp unit from the vehicle. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps /Lighting - Exterior/UNIT, Front Lamp - Removal) .
3. Rotate the headlamp leveling motor (4) on the back of the lamp housing counterclockwise about 30 degrees to unlock it from the housing.
4. Grasp the motor firmly with one hand and twist it toward the inboard side of the lamp far enough to disengage the ball on the end of the motor pushrod (3) from the saddle bracket (1) secured to the reflector (2) within the lamp housing.
5. Pull the motor and pushrod straight back and out of the front lamp unit housing.

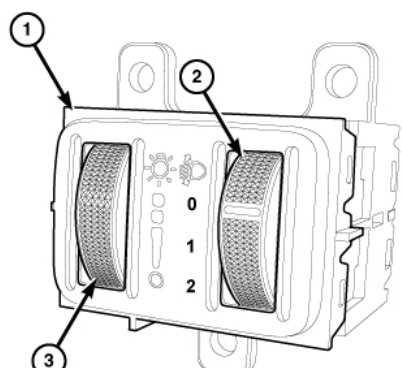
DESCRIPTION

The headlamp leveling switch (2) is used only on vehicles equipped with a manual remote headlamp leveling system manufactured for certain markets where the headlamp leveling system is required. The headlamp leveling switch is integral to the dimmer module, which includes the interior and panel lamps dimmer thumbwheel (3) and is mounted on the driver side of the instrument panel between the headlamp switch and the steering column. Only the switch face plate (1) and the thumbwheels are visible on the outer surface of the instrument panel.

The black plastic switch face plate has a stencil-like International Control and Display Symbol icon for **Headlamp Levelling Control** to clearly identify the function of the thumbwheel and the white numbers **0**, **1** and **2**, each of which indicates one of the three switch detent positions. Each higher number represents a lower aiming position of the headlamp beam relative to the road surface. Panel dimmer controlled Light Emitting Diode (LED) units soldered to the circuit board within the switch housing provide back lighting for visibility at night, but are not serviceable.



2985389

The black, molded plastic switch housing encloses the switch thumbwheel mechanism and the leveling switch circuitry including the switch contacts and a series resistor configuration. A connector receptacle is integral to the back of the switch housing. The dimming module with leveling switch has three mounting tabs that are secured by screws to the back of the headlamp switch bezel on the instrument panel. The dimming module is connected to the vehicle electrical system through a dedicated take out and connector of the instrument panel wire harness.

The headlamp leveling switch cannot be adjusted or repaired and, if the leveling switch or the dimmer switch is ineffective or damaged, the dimmer module unit must be replaced. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Interior/SWITCH, Dimmer - Removal) .

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The headlamp leveling switch receives a battery voltage input on a park/tail/running lamps feed circuit whenever the exterior lighting is turned ON. It then provides outputs to the Body Control Module (BCM) (also known as the Common Body Controller/CBC) on a headlamp leveling switch to module signal circuit to control the headlamp leveling function. The switch receives a path to ground at all times through a take out and eyelet terminal of the instrument panel wire harness secured to the instrument panel support structure.

The switch illumination level is controlled by a Pulse-Width Modulated (PWM) output received from the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) on a panel lamps driver circuit. The IC controls this output based upon the panel lamps dimmer signal circuit input from the panel lamps dimmer switch.

Each switch position selects a different tap on a series resistor within the switch to provide the appropriate resistor multiplexed output to the BCM over the headlamp leveling switch to module signal circuit. The BCM reads and responds to this input by providing the appropriate control outputs to the headlamp leveling motors.

The headlamp leveling switch as well as the hard wired inputs and outputs of the switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information.

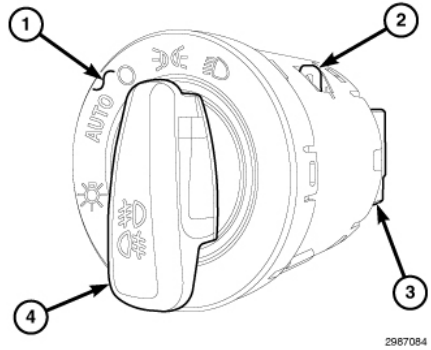
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The headlamp switch (1) is located on the instrument panel, in a cylinder-like mounting hole molded into the headlamp switch bezel to the left of the steering column. Several different switches are used, depending upon equipment and market requirements. The standard switch features a three-position rotary knob (4) for exterior lighting control. An optional switch has a fourth position added to the rotary knob for automatic headlamps and a momentary PUSH function added to the rotary knob for front fog lamp control.

Each of these switches is constructed of molded plastic. On vehicles with optional fog lamps the rotary knob also has the International Control and Display Symbol icon for **Front Fog Light** applied to it. The switch face plate is also labeled with graphics and icons to clearly identify the many functions of the rotary knob.

The switch housing is secured within the mounting hole of the instrument panel bezel by two spring loaded, pivoting pawl-like retainers (2), one near the bottom and another near the top. These pawls can be retracted for removal of the switch from the face of the instrument panel using a specific rotary knob actuation sequence. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/SWITCH, Headlamp - Removal) .



The back of the switch housing has an integral connector receptacle (3) containing terminal pins that connect the switch to the vehicle electrical system through a dedicated take out and connector of the instrument panel wire harness. A panel dimmer controlled Light Emitting Diode (LED) unit soldered to the circuit board within the switch provides back lighting for visibility at night, but is not serviceable.

The headlamp switch cannot be repaired and, if ineffective or damaged, it must be replaced.

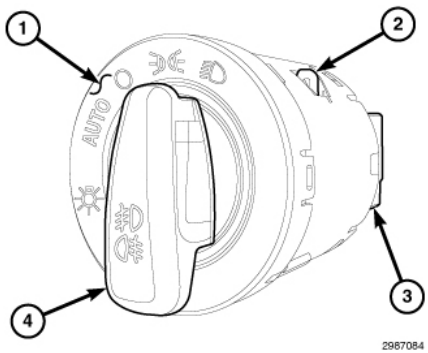
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: Before attempting to install the headlamp switch (1), be certain that both pawl-like retainers (2) are extended outward from the body of the switch. If the retainers are in the retracted position, rotating the headlamp switch rotary knob (4) to the OFF (O) position should disengage the retainer retractor mechanism causing the retainers to spring outward from the switch body.



1. Position the headlamp switch (1) close enough to the cylinder-like switch mounting hole in the instrument panel to reconnect the instrument panel wire harness connector to the connector receptacle (3) on the back of the switch housing.
2. Position and align the switch in the center of the switch mounting hole of the instrument panel.
3. Using hand pressure, press the switch firmly and evenly into the mounting hole until it is fully seated. An indication that the switch is fully seated will be a light audible click as each of the two pawl-like retainers (2) snap into place within the mounting hole.
4. Reconnect the battery negative cable.

OPERATION

The headlamp switch uses a single resistor multiplexed output to control the many functions and features it provides. The switch receives a clean ground from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) on a headlamp switch MUX return circuit. The BCM then reads the switch outputs using an internal pull up on the headlamp/fog lamp switch signal circuit to control the exterior lighting functions.

The switch illumination circuit receives a path to ground at all times through an instrument panel ground circuit. The illumination level is controlled by a Pulse-Width Modulated (PWM) output received from the BCM on a panel lamps driver circuit. The BCM controls this output based upon the panel lamps dimmer signal circuit input from the interior lighting thumbwheel switch in the dimmer module. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Interior/SWITCH, Dimmer - Operation) .

The headlamp switch operates as follows:

- **Front Fog Lamps Control** - For vehicles so equipped, the rotary knob on the headlamp switch is depressed to activate or deactivate the optional front fog lamps. The headlamp switch provides the appropriate resistor multiplexed output to the BCM over the headlamp/fog lamp switch signal circuit, and the BCM reads and responds to this input by energizing or de-energizing the right and left front and rear fog lamp control circuits through internal High Side Drivers (HSD) and by sending an electronic confirmation message to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) over the Controller Area Network (CAN) data bus, which controls the front and rear fog lamp indicators as appropriate.
- **Exterior Lighting Control** - The rotary knob on the headlamp switch is rotated to a detent position to activate or deactivate the exterior lighting. The headlamp switch provides the appropriate resistor multiplexed output to the BCM over the headlamp/fog lamp switch signal circuit, and the BCM responds by energizing or de-energizing the right and left park lamp feed circuits and the right and left high or low beam driver circuits through internal HSDs and by sending an electronic confirmation message to the IC over the CAN data bus, which controls the high beam indicator as appropriate. The BCM also remembers which headlamp beams were last selected with the multi-function switch, and energizes those beams by default the next time the headlamps are turned ON. If the vehicle is equipped with optional automatic headlamps and the **AUTO** (Automatic) position is selected, the BCM also monitors an electronic **ambient light level** message received over the CAN data bus from the air conditioner - heater control module based upon a hard wired input from the sun sensor to turn the exterior lighting ON and OFF automatically while the ignition switch is in the ON position.

The headlamp switch as well as the hard wired inputs and outputs of the switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information.

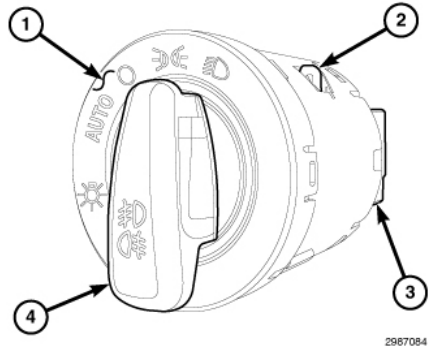
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Disconnect and isolate the battery negative cable.
2. Place the headlamp switch (1) rotary knob (4) in the OFF (**O**) position.
3. Push in on the rotary knob to engage the switch retainer (2) retractor mechanism.
4. Still holding the switch rotary knob depressed, rotate the knob clockwise toward the park lamps ON position to retract the two switch retainers. The retainers will be fully retracted before the rotary knob actually reaches the park lamps ON position.



5. With the switch rotary knob still in the retainer retractor position, pull the switch out of the cylinder-like mounting hole far enough to access and disconnect the instrument panel wire harness connector from the connector receptacle (3) on the back of the switch housing.
6. Remove the headlamp switch from the instrument panel.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

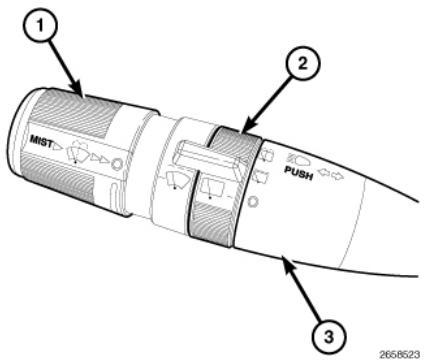
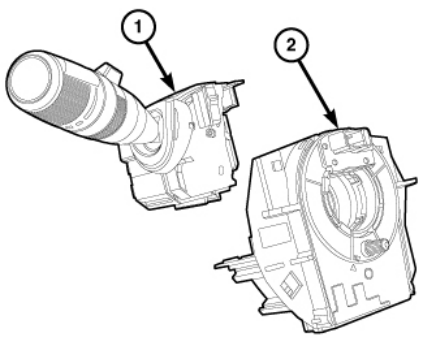
DESCRIPTION

The multi-function switch is located on the left side of the steering column, just below the steering wheel. This switch provides the primary controls for the front and rear wiper and washer systems, the turn signals and for headlamp beam selection. The only visible components of the switch are the control stalk (3), the control sleeve or ring (2) and the control knob (1) that extend through the shrouds on the left side of the steering column. The remainder of the switch including its mounting provisions, its electrical connection and the turn signal cancel actuator are concealed beneath the shrouds.



The switch housing (2) and controls (1) are constructed of molded black plastic. Each of the switch controls has white International Control and Display Symbol graphics applied to it, which clearly identify its many functions. A single integral latch feature (3) and slide tabs on the switch housing engage channels and a striker that are integral to the left side of the mounting bracket that is integral to the clockspring housing (5) that is secured to the top of the steering column.

The multi-function switch housing also contains an electronic circuit board and microprocessor that serve as a Local Interface Network (LIN) data bus slave node. The switch outputs are internally connected directly to the LIN slave node. An integral connector receptacle on the back of the switch housing connects the switch to the vehicle electrical system and to the LIN master node and Controller Area Network (CAN) data bus gateway integral to the Steering Angle Sensor (SAS) on the back of the clockspring housing through dedicated take outs and connectors of the instrument panel wire harness.



The multi-function switch provides the vehicle operator with a control interface for the following functions:

- **Front Washer Control** - The multi-function switch control knob provides a momentary WASH position for front washer system operation.
- **Front Wiper Control** - The multi-function switch control knob provides detent switching for two front continuous wipe switch positions, LOW speed or HIGH speed and an intermittent wipe mode with five DELAY interval positions. The control knob also has a front momentary MIST or pulse wipe feature switch position.
- **Headlamp Beam Selection** - The multi-function switch control stalk provides detent switching for selection of the headlamp HIGH or LOW beams.
- **Headlamp Optical Horn** - The multi-function switch control stalk includes momentary switching of the headlamp high beam circuits to provide an optical horn feature (sometimes referred to as flash-to-pass), which allows the vehicle operator to momentarily flash the headlamp high beams as an optical signalling device.
- **Rear Washer Control** - The multi-function switch control sleeve provides a momentary WASH position for rear washer system operation.
- **Rear Wiper Control** - The multi-function switch control sleeve provides detent switching for a single rear intermittent wipe mode.
- **Turn Signal Control** - The multi-function switch control stalk provides both momentary non-detent (lane change) switching or detent switching with automatic cancellation for both the left and right turn signals.

The multi-function switch cannot be adjusted or repaired. If any function of the switch is ineffective, or if the switch is damaged, the entire switch unit must be replaced. The clockspring (with the integral mounting bracket and the Steering Angle Sensor/SAS with the integral LIN master node and CAN gateway) as well as the multi-function switch (with the integral LIN slave node) are each available for separate service replacement.

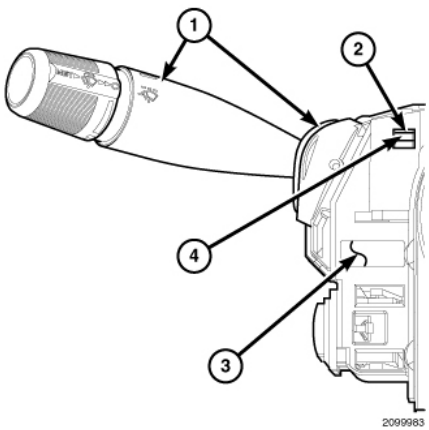
INSTALLATION

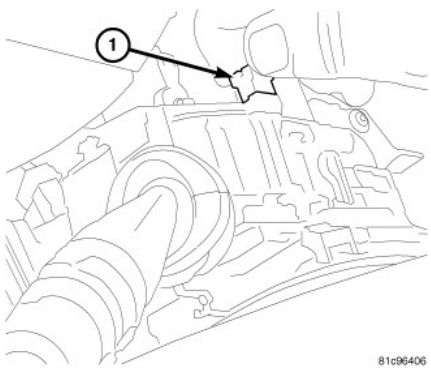
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor, or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Position the multi-function switch (1) housing over the receptacle in the mounting bracket (3) integral to the left side of the clockspring.
2. Slide the switch downward into the mounting bracket receptacle until it is fully seated and the tab (4) of the latch feature integral to the switch housing engages the access window (2) of the bracket.



3. Reconnect the instrument panel wire harness connector (1) to the connector receptacle on the back of the multi-function switch housing.
4. Reinstall the upper and lower shrouds onto the steering column. (Refer to 19 - Steering/Column/SHROUD, Steering Column - Installation) .
5. Reconnect the battery negative cable.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The multi-function switch is a Local Interface Network (LIN) data bus slave node to the Steering Angle Sensor (SAS) integral to the clockspring. The SAS is both a LIN data bus master node and a gateway to the Controller Area Network (CAN) data bus. The multi-function switch sends electronic **switch status** messages over the LIN data bus to the SAS, then the SAS relays electronic **switch request** messages over the CAN data bus to other electronic modules in the vehicle.

If the SAS detects no inputs from the multi-function switch, it transmits an electronic **Signal Not Available (SNA)** status message over the CAN data bus. The SNA status signals the other electronic modules to implement a fail-safe or default mode of operation. For the exterior lighting system, the multi-function switch fail-safe mode automatically selects LOW beams when the headlamps are turned ON. For the wiper system, the multi-function switch fail-safe mode will maintain the last selected wiper system mode of operation for the remainder of the current ignition cycle, after which the wiper system will default to LOW.

The hard wired circuits for the multi-function switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, the most reliable, efficient and accurate means to diagnose the electronics and messaging of this component requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

Following are descriptions of how the multi-function switch is operated to control the functions and features it provides:

- **Front Washer Control** - The control knob on the end of the multi-function switch control stalk is depressed toward the steering column to the momentary second detent position to activate the washer pump/motor in the FRONT WASH mode. The washer pump/motor will continue to operate for as long as the control knob is held in this position. The multi-function switch sends an electronic **front washer switch status** message over the LIN data bus to the SAS, which relays an electronic **front washer switch request** message over the CAN data bus to other electronic modules in the vehicle.
- **Front Wiper Control** - The control knob on the end of the multi-function switch control stalk is rotated to one of the two continuous front wiper detents, to one of five front intermittent wiper detents or to the OFF position to select the FRONT WIPER mode. The multi-function switch sends electronic **front wiper switch status** messages over the LIN data bus to the SAS, which relays an electronic **front wiper switch request** message over the CAN data bus to other electronic modules in the vehicle.
- **Front Wiper Mist Mode** - The control knob on the end of the multi-function switch control stalk is depressed toward the steering column to the momentary first detent position to activate the front wiper MIST mode. The wiper motor will continue to operate, one complete cycle at a time, for as long as the control knob is held in this position. The multi-function switch sends an electronic **front wiper switch status** message over the LIN data bus to the SAS, which relays an electronic **front wiper switch request** message over the CAN data bus to other electronic modules in the vehicle.
- **Headlamp Beam Selection** - The headlamp high beams are selected when the multi-function switch control stalk is pushed forward to the high beam selection detent position. The low beams are selected when the control stalk is pulled rearward to the low beam selection detent position. The multi-function switch sends an electronic **beam select switch status** message over the LIN data bus to the SAS, which relays an electronic **beam select switch request** message over the CAN data bus to other electronic modules in the vehicle.
- **Headlamp Optical Horn** - The headlamp optical horn is selected each time the multi-function switch control stalk is pulled fully rearward to a momentary position. The headlamp HIGH beams will remain illuminated for as long as the control stalk is held in this momentary position and the LOW beams will be restored when the control stalk is released. The multi-function switch sends an electronic **headlamp optical horn switch status** message over the LIN data bus to the SAS, which relays an electronic **headlamp optical horn switch request** message over the CAN data bus to other electronic modules in the vehicle.
- **Rear Washer Control** - The control sleeve on the multi-function switch control stalk is rotated counterclockwise toward the instrument panel to the momentary WASH position to activate the washer pump/motor in the REAR WASH mode. The washer pump/motor will continue to operate for as long as the control sleeve is held in this position. The multi-function switch sends an electronic **rear washer switch status** message over the LIN data bus to the SAS, which relays an electronic **rear washer switch request** message over the CAN data bus to other electronic modules in the vehicle.
- **Rear Wiper Control** - The control sleeve on the multi-function switch control stalk is rotated clockwise away from the instrument panel to the rear intermittent wiper detent to select the REAR WIPER mode. The multi-function switch sends an electronic **rear wiper switch status** message over the LIN data bus to the SAS, which relays an electronic **rear wiper switch request** message over the CAN data bus to other electronic modules in the vehicle.
- **Turn Signal Control** - The turn signals are requested when the multi-function switch control stalk is moved downward (LEFT signal) or upward (RIGHT signal). The control stalk has a detent position in each direction that provides turn signals with automatic cancellation, and an intermediate, momentary position in each direction that automatically provides three turn signal blinks as a LANE CHANGE feature when the control stalk is tapped or will energize the turn signals for as long as the control stalk is held in the momentary position. When the control stalk is moved to a detent turn signal switch position, a cancel actuator extends from the multi-function switch housing through an opening in the side of the clockspring case toward the center of the steering column. A turn signal cancel cam that is integral to the clockspring rotor rotates with the steering wheel and the cam lobes contact the cancel actuator when it is extended from the multi-function switch. When the steering wheel is rotated during a turning maneuver, one of the turn signal cancel cam lobes will contact the turn signal cancel actuator. The cancel actuator latches against the cancel cam rotation in the direction opposite that which is signaled. If the LEFT turn signal detent is selected, the lobes of the cancel cam will ratchet past the cancel actuator when the steering wheel is rotated to the left, but will unlatch the cancel actuator as the steering wheel rotates to the right and returns to center, which will cancel the turn signal event and release the control stalk from the detent so it returns to the neutral OFF position. The multi-function switch sends an electronic **turn signal switch status** message over the LIN data bus to the SAS, which relays an electronic **turn signal switch request** message over the CAN data bus to other electronic modules in the vehicle.

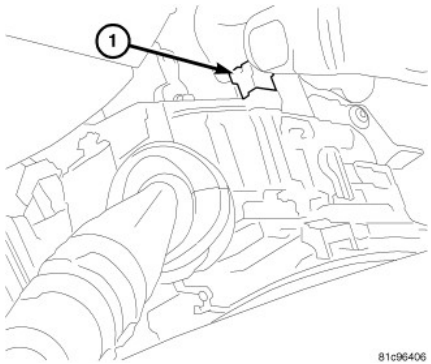
REMOVAL

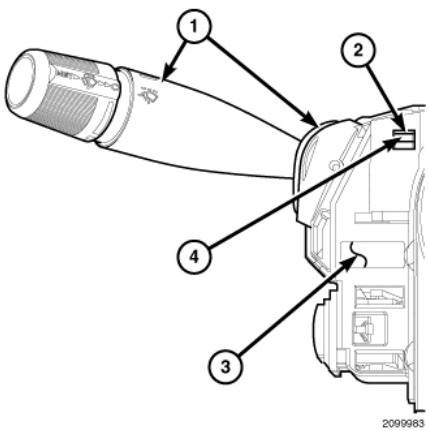
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor, or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Disconnect and isolate battery negative cable.
2. Remove the upper and lower shrouds from the steering column. (Refer to 19 - Steering/Column /SHROUD, Steering Column - Removal)
3. Disconnect the instrument panel wire harness connector (1) from the connector receptacle on the back of the multi-function switch housing.



4. Working through the access window (2) of the mounting bracket (3) integral to the left side of the clockspring, depress the tab (4) of the latch feature integral to the multi-function switch (1) housing far enough to disengage the latch.
5. While holding the latch disengaged, slide the switch upward and out of the receptacle in the mounting bracket.



OPERATION

Following are paragraphs that briefly describe the operation of each of the major exterior lighting systems. The lamps and the hard wired circuits between components related to the exterior lighting system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the exterior lighting system or the electronic controls or communication between modules and other devices that provide some features of the exterior lighting system. The most reliable, efficient and accurate means to diagnose the exterior lighting system or the electronic controls and communication related to exterior lighting system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

AUTOMATIC HEADLAMPS

The optional automatic headlamp system includes the headlamp switch, the Body Control Module (BCM) (also known as the Common Body Controller/CBC), the heater and air conditioner control unit and the sun load sensor on the top of the instrument panel.

The sun load sensor provides an ambient light level input to the A/C - heater control whenever the ignition switch is in the ON position. The A/C - heater control responds to this input by sending the appropriate electronic **light level** messages to the BCM over the Controller Area Network (CAN) data bus. When the **AUTO** (Automatic) position is selected with the headlamp switch, the BCM receives a hard wired multiplex input from the headlamp switch. The BCM also receives electronic messages over the CAN data bus from the PCM indicating the engine is running.

The BCM responds to these input conditions by automatically controlling a Pulse-Width Modulated (PWM) voltage output to the selected headlamp bulb filaments through the right and left low or high beam driver circuits to illuminate the headlamps. The BCM also remembers which beams (low or high) were selected when the headlamps were last turned OFF, and energizes those beams and lamps again the next time it turns the headlamps ON.

BACKUP LAMPS

The backup (or reverse) lamps have a path to ground at all times through a takeout and eyelet terminal of the body wire harness that is secured to the body sheet metal within the passenger compartment. On vehicles with a manual transmission, the backup lamp switch provides an input to the BCM through a backup lamp switch signal circuit, and the BCM provides battery voltage to the backup lamps on the backup lamp control output circuit whenever the ignition switch is in the ON position and the REVERSE position is selected with the transmission shift linkage.

On vehicles with an automatic transmission, the Powertrain Control Module (PCM) continually monitors a hard wired multiplex input from the Transmission Range Sensor (TRS), then sends the appropriate electronic **transmission gear selector status** messages to other electronic modules over the CAN data bus. Whenever the ignition switch is in the ON position and the BCM receives an electronic message indicating the status of the transmission gear selector is REVERSE, it provides a battery voltage output to the backup lamps on the backup lamp control output circuit.

BRAKE LAMPS

The brake (or stop) lamps and the Center High Mounted Stop Lamp (CHMSL) each have a path to ground at all times through a takeout and eyelet terminal of the body wire harness that is secured by a ground screw to the body sheet metal within the passenger compartment. The Controller Antilock Brake (CAB) (also known as the Antilock Brake Module/ABM) monitors a hard wired input from the brake pedal position sensor, which is actuated by movement of the brake pedal arm. When the CAB receives an input from the brake pedal position sensor indicating movement of the brake pedal arm it responds by sending the appropriate electronic **brake lamp switch** status message to the BCM over the CAN data bus. The BCM then controls brake lamp and CHMSL illumination through High Side Drivers (HSD) on the left and right stop lamp control circuits. The brake lamp function of the trailer tow wiring is also controlled by an output from the BCM based upon the electronic **brake lamp switch** status messages received from the CAB.

DAYTIME RUNNING LAMPS

Vehicles equipped with this option or manufactured for sale in Canada illuminate the high beam filament of both headlamps at a reduced intensity when the engine is running, the parking brake is released and the exterior lamps are turned OFF. The BCM must be programmed appropriately for this feature to be enabled. Once enabled, anytime the BCM receives electronic messages over the CAN data bus from the PCM indicating the engine is running, a hard wired multiplex input from the headlamp switch indicating the status of the headlamp switch is OFF and a hard wired input from the park brake switch indicating that the parking brake is released, the BCM provides a PWM voltage output to the proper headlamp bulb filaments through the right and left high beam feed circuits to produce illumination at a reduced intensity.

FRONT FOG LAMPS

Vehicles equipped with optional front fog lamps include a front fog lamp switch integral to the headlamp switch on the instrument panel. The front fog lamps have a path to ground at all times through their connection to the headlamp and dash wire harness and a takeout with an eyelet terminal that is secured to the body sheet metal. The BCM monitors a hard wired multiplex input from the headlamp switch to determine whether the fog lamps are selected.

When the BCM input from the headlamp switch indicates the fog lamps are selected, it controls front fog lamp operation by providing a battery voltage output to the fog lamps through the right and left front fog lamp control circuits. The BCM also sends the appropriate electronic messages to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) to illuminate or extinguish the front fog lamp indicator. The BCM will automatically de-energize the front fog lamps any time the headlamp high beams are selected, except on vehicles manufactured for certain export markets.

The BCM also provides a battery saver (load shedding) feature for the front fog lamps, which will turn these lamps OFF if they are left ON for more than about eight minutes with the ignition switch in the LOCK position, if there is a charging system failure, or if the electrical system voltage falls below about 11.75 volts for more than about 30 seconds.

Each front fog lamp includes an integral adjustment screw to be used for static aiming of the fog lamp beams.

HAZARD WARNING LAMPS

The hazard warning system includes the IC, the BCM and the hazard switch in the instrument panel switch bank of the Integrated Center Stack (ICS) module located in the center stack area of the instrument panel. The hazard switch provides a hard wired input to the BCM. When the BCM receives an input from the hazard switch, it controls hazard warning system operation and flash rate by controlling battery voltage outputs through high side drivers on the front and rear, right and left turn signal control circuits. On vehicles manufactured for certain export markets where they are required, the BCM provides battery voltage to the repeater lamps through right and left repeater lamp control output circuits based upon the hazard switch input.

The BCM also sends the appropriate electronic messages to the IC over the CAN data bus to control the illumination and flash rate of the right and left turn signal indicators, as well as to control the click rate of an electromechanical relay soldered onto the IC electronic circuit board that emulates the sound emitted by a conventional electromechanical hazard warning flasher.

HEADLAMPS

The headlamp system includes the IC, the BCM, the headlamp switch on the instrument panel, the Steering Column Module (SCM), the Steering Angle Sensor (SAS) and the multi-function switch on the steering column. The headlamp bulbs have a path to ground at all times through their connection to the headlamp and dash wire harness. The headlamp and dash wire harness has takeouts with eyelet terminals that are secured to the body sheet metal. The BCM will store a Diagnostic Trouble Code (DTC) for any shorts or opens in the headlamp circuits.

The BCM monitors a hard wired multiplex input to determine the status of the headlamp switch on the instrument panel, while the SCM monitors a hard wired multiplex input from the multi-function switch to determine whether the headlamp high or low beams are selected. The SCM sends the appropriate **headlamp beam select switch status** messages to the SAS over the LIN data bus. The SAS then relays the appropriate electronic **headlamp beam request** messages to the BCM over the CAN data bus. The BCM responds to these input conditions by controlling a PWM voltage output to the headlamps through high side drivers on the right and left low and high beam feed circuits to illuminate the selected headlamp filaments. The BCM also sends the appropriate electronic messages to the IC to control the illumination of the high beam indicator.

When the optical horn feature is selected, the low beams will shut OFF about 200 milliseconds after the high beams are activated. The BCM also remembers which beams (LOW or HIGH) were selected when the headlamps were last turned OFF, and energizes those beams again the next time the headlamps are turned ON. The BCM provides a battery saver (load shedding) feature for the headlamps, which will turn these lamps OFF if they are left ON for more than about eight minutes with the ignition switch in the LOCK position.

The SCM provides a fail-safe feature for the headlamps, which will cause the BCM to turn the low beam headlamps ON automatically if there is no input available from the multi-function switch. The BCM provides a fail-safe feature for the headlamps, which will turn the low beam headlamps ON automatically if there is no input available from the headlamp switch. The BCM also provides a fail-safe feature for the headlamps that will turn the headlamps ON automatically whenever a loss of LIN bus or CAN bus communication is detected with the ignition switch in the ON position.

Each headlamp includes integral reflector adjustment screws to be used for static aiming of the headlamps.

HEADLAMP LEVELING

In certain export markets where required, a headlamp leveling system is provided on the vehicle. The headlamp leveling system includes unique front lamp units each equipped with a headlamp leveling actuator motor, and a thumbwheel-actuated headlamp leveling switch integral to the dimmer module in the instrument panel. The headlamp leveling system allows the headlamp beams to be adjusted to one of three vertical positions to compensate for changes in inclination caused by the loading of the vehicle suspension. The leveling motors are mechanically connected through an integral pushrod to the adjustable headlamp reflector.

Each time the headlamp leveling switch is moved the circuitry of the switch provides a hard wired multiplex input to the BCM. The BCM responds to these messages inputs by providing a voltage output to the headlamp leveling motors through a high side driver on the headlamp level sensor signal circuit to move the headlamp reflectors to the selected position based upon the voltage input received from the BCM.

The BCM logic will only allow the headlamp leveling system to operate while the ignition switch is in the ON position and the exterior lighting is turned ON.

HEADLAMP TIME DELAY

The headlamp time delay feature includes the headlamp switch and the BCM. This feature is customer programmable using the Electronic Vehicle Information Center (EVIC) switches and the U-Connect Touch™ screen module in the Integrated Center Stack (ICS). If the headlamp switch is in the **AUTO** (Automatic) position when the ignition switch is moved from the ON position to any position except ON, then the headlamps will remain illuminated until after the selected delay interval has elapsed. The park lamps will not stay ON during the headlamp time delay interval. The default delay interval is 90 seconds, but can be reprogrammed by the customer using the EVIC switches.

PARK LAMPS

The park lamps system includes the headlamp switch on the instrument panel and the BCM. The front park lamp, side marker lamp and, on vehicles manufactured for certain export markets, position lamp bulbs each have a path to ground at all times through their connection to the headlamp and dash wire harness. The headlamp and dash wire harness has takeouts with eyelet terminals that are secured to the body sheet metal. The rear park/tail lamp, side marker lamp and license plate lamp bulbs each have a path to ground at all times through a takeout and eyelet terminal of the body wire harness that is secured by a ground screw to the body sheet metal.

The BCM monitors a hard wired multiplex input from the headlamp switch. The BCM responds to this input by controlling a battery voltage output to the appropriate lamp bulbs through high side drivers on the front and rear, right and left lamp driver and control circuits.

The BCM provides a battery saver (load shedding) feature for the park lamps, which will turn these lamps OFF if they are left ON for more than about eight minutes with the ignition switch in the LOCK position. The BCM also provides a fail-safe feature for the park lamps, which will turn the park lamps and low beam headlamps ON automatically if there is no input available from the headlamp switch. The BCM also provides a fail-safe feature for the park lamps that will turn the park lamps and low beam headlamps ON automatically whenever a loss of CAN bus communication is detected with the ignition switch in the ON position.

REAR FOG LAMPS

Rear fog lamps are installed on vehicles manufactured for certain export markets where they are required. The rear fog lamp system includes the headlamp switch, the IC and the BCM. The rear fog lamp bulbs have a path to ground at all times through a takeout and eyelet terminal of the body wire harness that is secured to the body sheet metal.

The BCM monitors a hard wired multiplex input from the headlamp switch to determine whether the rear fog lamps are selected. The BCM responds to this input by controlling a battery voltage output to the rear fog lamp bulbs through a high side driver on the rear fog lamp signal control circuit. The BCM also sends the appropriate electronic messages to the IC to control the rear fog lamp indicator.

The BCM will automatically energize and de-energize the front fog lamps in concert with the rear fog lamps. The BCM also provides a battery saver (load shedding) feature for the rear fog lamps, which will turn these lamps OFF if they are left ON for more than about eight minutes with the ignition switch in the LOCK position.

TRAILER TOW WIRING

Vehicles equipped with an optional trailer tow preparation package are shipped from the factory with a trailer tow wiring harness and 4-pin trailer connector that is packaged with an instruction card and placed in the glove box of the vehicle. The trailer tow harness includes three relays designed to isolate the trailer park lamps as

well as right and left turn signal and stop lamp lighting from the rear vehicle lighting and prevent overloading of the park, turn signal and stop lamp lighting drivers in the BCM. These vehicles also include a dedicated trailer tow park lamp control output circuit protected by a 15 ampere fuse located in the BCM.

If the trailer lighting is connected directly to the vehicle wiring without using the necessary relays, the vehicle electrical system will become overloaded and the rear lighting of the vehicle will cease to function. The BCM will store a Diagnostic Trouble Code (DTC) for this condition.

TURN SIGNAL LAMPS

The turn signal lamps system includes the multi-function switch on the steering column, the SCM, the SAS, the IC and the BCM. The front turn signal lamp bulbs each have a path to ground at all times through their connection to the headlamp and dash wire harness. The headlamp and dash wire harness has takeouts with eyelet terminals that are secured to the body sheet metal. The rear turn signal lamp bulbs have a path to ground at all times through a takeout and eyelet terminal of the body wire harness that is secured by a ground screw to the body sheet metal.

The SCM monitors a hard wired multiplex input from the multi-function switch to determine the status of the turn signal switch, then sends the appropriate electronic **turn signal switch status** messages to the SAS over the LIN data bus. The SAS relays the appropriate electronic **turn signal request** messages to the BCM over the CAN data bus. The BCM responds to these messages by controlling a battery voltage output and the flash rate for either the right or left turn signal lamps through high side drivers on the appropriate front and rear, right or left turn signal control circuits. The BCM also sends the appropriate electronic messages to the IC to control the illumination and flash rate of the right or left turn signal indicators, as well as to control the click rate of an electromechanical relay soldered onto the IC electronic circuit board that emulates the sound emitted by a conventional electromechanical turn signal flasher.

The BCM also provides a Turn Signal ON warning that will send a **turn signal ON warning** request message to the IC over the CAN bus that causes the IC to generate repetitive chimes to indicate that a turn signal has been active continuously for 1.6 kilometers (1 mile) with the vehicle speed greater than 22 kilometers-per-hour (15 miles-per-hour). Vehicles built for markets other than the United States and Canada have a revised distance threshold of 4 kilometers (2.49 miles) for this feature. The chime will continue until the turn signal input becomes inactive or until the vehicle speed message indicates that the speed is less than 22 kilometers-per-hour (15 miles-per-hour), whichever occurs first.

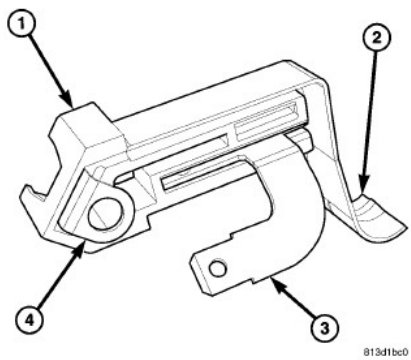
DESCRIPTION

There are two unique park brake switches used on this vehicle, depending upon whether the vehicle has a foot-operated or hand-operated park brake lever mechanism.

FOOT-OPERATED

The foot-operated park brake switch (1) is located on the park brake lever mechanism on the cowl side inner panel below the instrument panel, outboard of the steering column. This switch includes a spade-type output terminal (3) that connects the switch to the vehicle electrical system through a dedicated take out and connector of the body wire harness. The output terminal is integral to the stationary contact within a molded plastic insulator.



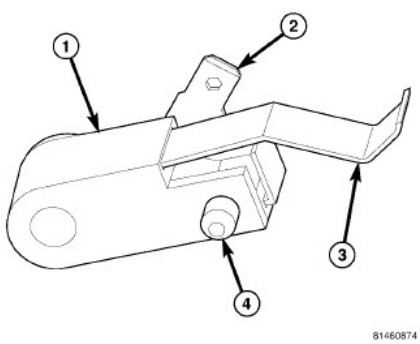
Foot-Operated Park Brake Switch

A locating tab on the insulator engages a slot in the park brake lever mechanism for positive switch location. External to the insulator is a movable leaf contact with an integral grounding lug (4) on one end and an integral actuating lever and follower (2) on the opposite end. The switch is secured to and grounded by a single screw to the park brake lever mechanism.

The foot-operated park brake switch cannot be adjusted or repaired and, if ineffective or damaged, it must be replaced.

HAND-OPERATED

The hand-operated park brake switch (1) is located on the park brake lever mechanism on the floor panel transmission tunnel below the center floor console. This switch includes a spade-type output terminal (2) that connects the switch to the vehicle electrical system through a dedicated take out and connector of the body wire harness. The output terminal is integral to the stationary contact within a molded plastic insulator.



Hand-Operated Park Brake Switch

A locating tab (4) on the insulator engages a slot in the park brake lever mechanism for positive switch location. External to the insulator is a movable leaf contact (3) with an integral grounding lug on one end and an integral actuating lever and follower on the opposite end. The switch is secured to and grounded by a single screw to the park brake lever mechanism.

The hand-operated park brake switch cannot be adjusted or repaired and, if ineffective or damaged, it must be replaced.

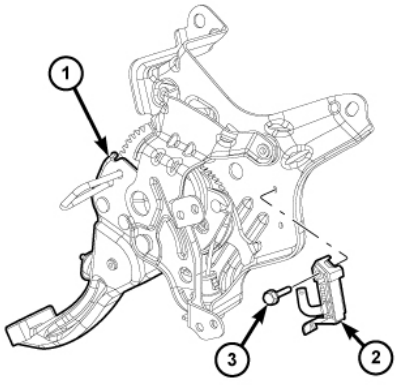
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

FOOT-OPERATED

1. Reach under the outboard end of the instrument panel to position the park brake switch (2) onto the park brake lever mechanism (1) on the cowl side inner panel. Be certain to engage the locating pin on the back of the switch insulator into the locating slot in the lever mechanism bracket.
2. Install and tighten the screw (3) that secures the park brake switch to the park brake lever mechanism. Tighten the screw to 2.5 N·m (24 in. lbs.).
3. Reconnect the wire harness connector to the terminal of the park brake switch.
4. Reconnect the battery negative cable.

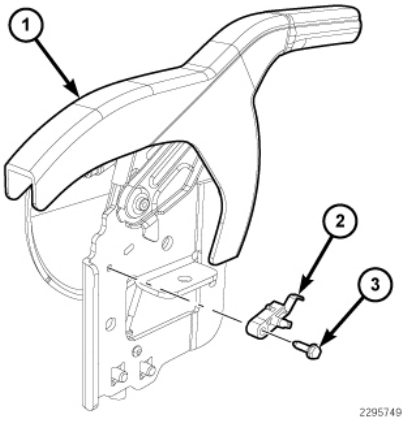


2295829

5. Turn the ignition switch to the ON position and check for proper brake indicator operation with the parking brake applied, then release the parking brake and check that the brake indicator extinguishes.

HAND-OPERATED

1. Position the park brake switch (2) onto the right side of the park brake lever (1) bracket. Be certain to engage the locating pin on the back of the switch insulator into the locating slot in the lever bracket.
2. Install and tighten the screw (3) that secures the switch to the lever bracket. Tighten the screw to 2.5 N·m (24 in. lbs.).
3. Reconnect the wire harness connector to the terminal of the switch.
4. Reinstall the console onto the floor panel. (Refer to 23 - Body/Interior/CONSOLE, Center - Installation) .



2295749

5. Reconnect the battery negative cable.
6. Turn the ignition switch to the ON position and check for proper brake indicator operation with the parking brake applied, then release the parking brake and check that the brake indicator extinguishes.

OPERATION

Both the foot-operated and the hand-operated park brake switch are normally closed, mechanically actuated leaf contact switches that are operated by the foot or hand park brake lever mechanism. The switch is grounded through its mounting to the park brake lever mechanism and provides a ground input to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) on a park brake switch sense circuit whenever the park brake is applied, and opens this circuit whenever the park brake is released. The park brake switch sense input to the IC is used as an additional logic input by the IC for control of the brake indicator and may also be used as a logic input for other electronic features in the vehicle.

The park brake switch as well as the hard wired inputs and outputs of the switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between other modules and devices that rely upon inputs from the park brake switch. The most reliable, efficient, and accurate means to diagnose the electronic controls and communication related to park brake switch operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

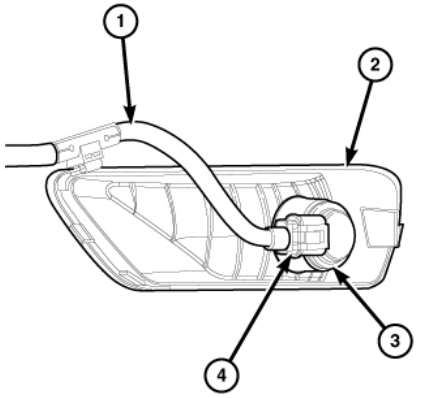
BULB

Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**

NOTE: The following procedure applies only to vehicles manufactured for certain export markets where rear fog lamps are optional or required equipment. In North American markets, a rear reflex (reflector) is installed in each rear fascia opening used for the rear fog lamps, but rear fog lamps are not available in vehicles manufactured for North American markets.

1. Align the base of the rear fog lamp bulb with the bulb socket (3).
2. Push the bulb straight into the socket until the base is firmly seated.
3. Align the socket and bulb with the keyed opening on the back of the rear fog lamp housing (2).
4. Insert the socket and bulb into the housing until the socket is firmly seated.
5. Rotate the socket clockwise about 30 degrees to lock it into place.



2757252

6. Position the lamp close enough to the rear fascia opening to access and reconnect the rear fascia wire harness (1) connector (4) to the lamp socket on the back of the lamp housing.
7. Reinstall the rear fog lamp into the rear fascia. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/LAMP, Fog - Installation) .
8. Reconnect the battery negative cable.

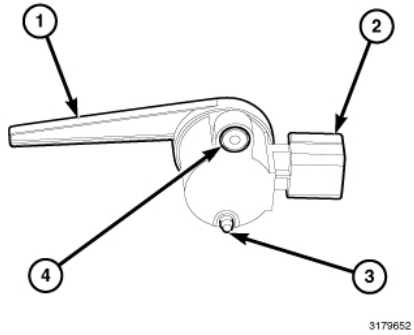
DESCRIPTION

A brake pedal position sensor is used in place of the brake (or stop) lamp switch in this vehicle. This sensor has a spring-loaded mechanical lever arm (1) that is actuated by a pin integral to the brake pedal arm. The sensor is secured by an integral locating pin (3) and a single screw through a threaded metal insert in an integral mounting tab (4) to the brake pedal support bracket under the instrument panel on the driver side of the vehicle.

The molded plastic sensor housing has an integral connector receptacle (2) containing three terminal pins. The switch is connected to the vehicle electrical system through a dedicated take out of the body wire harness. A cavity in the center of the molded plastic sensor housing contains the electronic circuitry of the sensor. The sensor housing is sealed to enclose and protect the internal electronic circuitry and components.



The brake pedal position sensor cannot be repaired. If the sensor is damaged or ineffective it must be replaced with a new unit.

2014 Dodge JC - DODGE JOURNEY

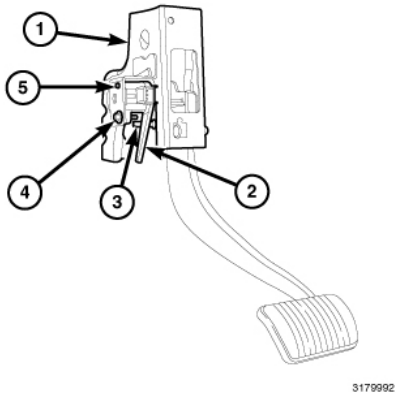
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Depress and hold the brake pedal in the depressed position.
2. Position the brake pedal position sensor to the sensor bracket on the brake pedal support bracket (1).
3. Engage the sensor locating pin (5) into the locating hole in the sensor bracket.
4. Install and tighten the screw (4) that secures the sensor to the sensor bracket. Tighten the screw securely.



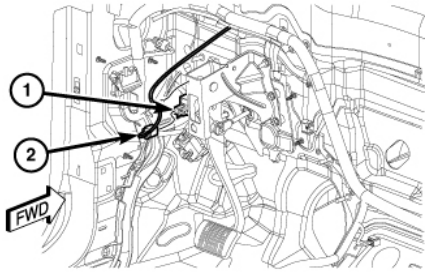
3179992

CAUTION: **Brake booster damage may occur if the brake pedal pull exceeds about 9 kilograms (20 pounds).**

5. Release the brake pedal. Then pull the pedal lightly upward to be certain the pedal is in its normal at-rest position.

NOTE: Be certain the brake pedal position sensor is fully seated in the sensor bracket before completing the electrical connection.

6. Reconnect the body wire harness connector (2) to the connector receptacle on the sensor (1).
7. If equipped, reinstall the silencer pad below the steering column. (Refer to 23 - Body/Instrument Panel/PANEL, Silencer - Installation) .



3179931

8. Reconnect the battery negative cable.

NOTE: Whenever the brake pedal position sensor is removed and reinstalled or replaced with a new unit, it is necessary for the Controller Antilock Brake (CAB) (also known as the Antilock Brake Module/ABM or Antilock Brake System/ABS module) to calibrate the reinstalled or the new sensor. Follow the programming steps outlined in the diagnostic scan tool for the “ABS Initialize” routine under “Miscellaneous Functions” for the “ABS Module” menu item as appropriate.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The brake pedal position sensor monitors changes in the brake pedal position relative to the brake pedal mounting bracket. The sensor circuitry is energized by the Controller Antilock Brake (CAB) (also known as the Antilock Brake Module/ABM or Antilock Brake System/ABS module) and provides hard wired analog (potentiometer) inputs back to the CAB. The CAB uses the sensor inputs directly as additional logic for many of the Antilock Brake System (ABS), Electronic Stability Control (ESC) and Brake Assist System (BAS) features.

The CAB also sends electronic **brake lamp switch status** messages to other electronic modules in the vehicle over the Controller Area Network (CAN) data bus. Other electronic modules use this information as an additional logic input for controlling many other vehicle functions and features, including the Body Control Module (BCM) (also known as the Common Body Controller/CBC) for control of the brake (or stop) lamps.

The hard wired circuits between the brake pedal position sensor and the CAB may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the brake pedal position sensor or the electronic controls and communication that provide some features related to brake pedal position sensor operation. The most reliable, efficient and accurate means to diagnose the brake pedal position sensor or the electronic controls and communication related to sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

BULB

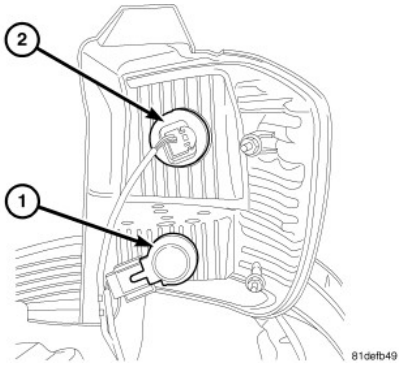
Labor Operations: Click to display a list of Labor Operations associated with this procedure

Each rear lamp unit for this vehicle consists of two pieces. An outer rear lamp unit that is secured at the rear of each quarter panel includes either a single incandescent bulb or multiple Light-Emitting Diode (LED) units for the park (or tail) lamps, the brake (or stop) lamps and an incandescent bulb for the turn signal lamps. An inner rear lamp is secured on each outboard side of the liftgate outer panel adjacent to the outer lamp and also includes either a single incandescent or multiple LED units for the park (or tail) lamps as well as an incandescent bulb for the backup (or reverse) lamps. The incandescent bulbs are available for individual service replacement; however, if an LED unit is ineffective or damaged, the entire inner or outer rear lamp unit must be replaced.

OUTER LAMP

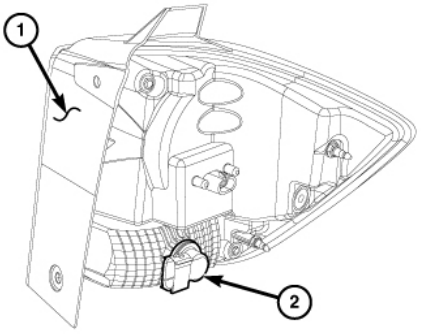
CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**

NOTE: In vehicles manufactured for domestic markets except with LED lighting, the outer rear lamp unit contains a single bulb (1) for tail/stop/rear side marker/turn signal functions. In vehicles manufactured for export markets except with LED lighting, the outer rear lamp unit contains two bulbs. They are the tail/stop/rear side marker (1) and the turn signal (2). The service procedures for each bulb are the same, only the bulb sizes and types may differ.



Except With LED Lighting

1. Align the base of the bulb with the appropriate bulb socket (1 or 2).
2. Push the bulb straight into the socket until the base is firmly seated.
3. Align the socket and bulb with the keyed opening on the back of the outer rear lamp unit housing.
4. Insert the socket and bulb into the housing until the socket is firmly seated.
5. Rotate the socket clockwise about 30 degrees to lock it into place.
6. Reinstall the outer rear lamp unit onto the vehicle. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/LAMP, Tail Stop Turn - Installation) .
7. Reconnect the battery negative cable.

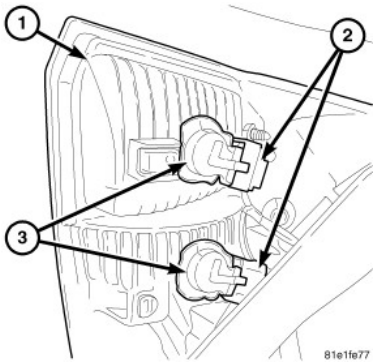


With LED Lighting

INNER LAMP

CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**

NOTE: Except with LED lighting, the inner rear lamp unit contains two bulbs. The upper socket contains the tail lamp bulb, while the lower socket contains the backup lamp bulb. The service procedures for each bulb are the same, only the bulb sizes and types may differ.



Except With LED Lighting

1. Align the base of the bulb with the bulb socket (2).
2. Push the bulb straight into the socket until the base is firmly seated.
3. Align the socket and bulb with the keyed opening on the back of the inner rear lamp unit housing (2).
4. Insert the socket and bulb into the housing until the socket is firmly seated.
5. Rotate the socket clockwise about 30 degrees to lock it into place.
6. Reinstall the inner rear lamp unit (1) onto the vehicle. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/LAMP, Tail Stop Turn - Installation) .
7. Reconnect the battery negative cable.

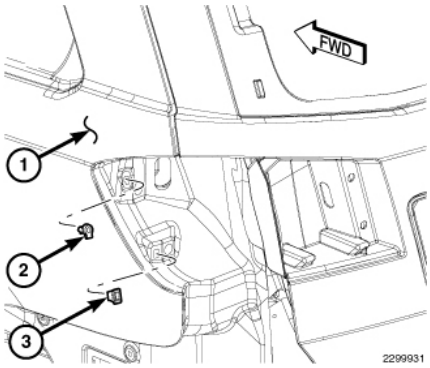
Labor Operations: Click to display a list of Labor Operations associated with this procedure

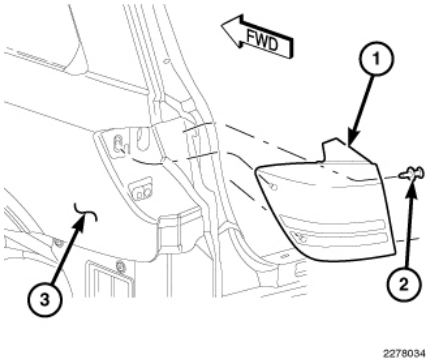
Each rear lamp unit for this vehicle consists of two pieces. An outer rear lamp unit that is secured at the rear of each quarter panel includes multiple Light-Emitting Diode (LED) units for the park (or tail) lamps and the brake (or stop) lamps and an incandescent bulb for the turn signal lamps. An inner rear lamp is secured on each outboard side of the liftgate outer panel adjacent to the outer lamp and also includes multiple LED units for the park (or tail) lamps as well as an incandescent bulb for the backup (or reverse) lamps. The outer and inner rear lamp units are serviced individually.

OUTER

1. Check to be certain that the two plastic grommets (2 and 3) are in good condition and properly installed in the outboard side of the lamp opening of the body sheet metal (1).



2. Position the outer rear lamp unit (1) to the lamp opening of the body sheet metal (3).
3. Reconnect the two body wire harness connectors to the LED lighting element and the bulb socket connector receptacles on the back of the lamp housing.
4. Align the two locating pins on the back of the lamp housing with the plastic grommets in the lamp opening of the body sheet metal.
5. Using hand pressure, push firmly and evenly on the outboard top and bottom of the lamp until both alignment pins snap into the grommets.



6. Reinstall the two push pin fasteners (2) that secure the inboard side of the outer rear lamp unit to the side jamb of the liftgate opening.
7. Reconnect the battery negative cable.

INNER

1. Check to be certain that the two plastic grommets are in good condition and properly installed on the inboard side of the liftgate (1) lamp opening. If a grommet is removed, it must be replaced with a new unit.
2. Check to be certain that the two U-nuts are in good condition and properly installed on the outboard side of the inner rear lamp unit (2).

3. Position the lamp to the liftgate lamp opening.

4. Reconnect the two liftgate wire harness connectors (2) to the LED lighting element and the bulb socket connector receptacles on the back of the lamp housing.

5. Align the two locating pins on the back of the lamp housing with the plastic grommets in the liftgate (1) lamp opening.

6. Using hand pressure, push firmly and evenly on the inboard top and bottom of the lamp until both alignment pins snap into the grommets.

7. Install and tighten the two screws (3) that secure the outboard side of the inner rear lamp unit to the liftgate lamp opening. Tighten the screws to 1.5 N·m (15 in. lbs.).

8. Reconnect the battery negative cable.

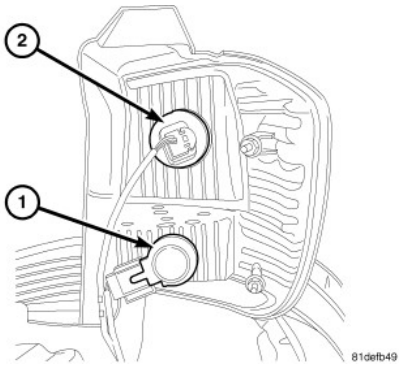
Each rear lamp unit for this vehicle consists of two pieces. An outer rear lamp unit that is secured at the rear of each quarter panel includes either a single incandescent bulb or multiple Light-Emitting Diode (LED) units for the park (or tail) lamps, the brake (or stop) lamps and an incandescent bulb for the turn signal lamps. An inner rear lamp is secured on each outboard side of the liftgate outer panel adjacent to the outer lamp and also includes either a single incandescent or multiple LED units for the park (or tail) lamps as well as an incandescent bulb for the backup (or reverse) lamps. The incandescent bulbs are available for individual service replacement; however, if an LED unit is ineffective or damaged, the entire inner or outer rear lamp unit must be replaced.

OUTER LAMP

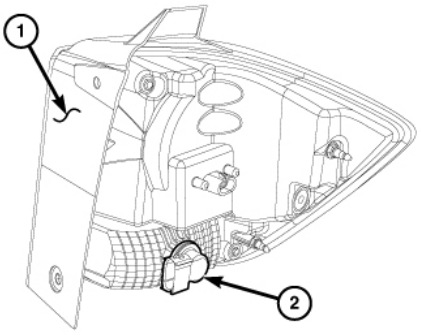
NOTE:

In vehicles manufactured for domestic markets except with LED lighting, the outer rear lamp unit contains a single bulb (1) for tail/stop/rear side marker/turn signal functions. In vehicles manufactured for export markets except with LED lighting, the outer rear lamp unit contains two bulbs. They are the tail/stop/rear side marker (1) and the turn signal (2). The service procedures for each bulb are the same, only the bulb sizes and types may differ.



Except With LED Lighting

1. Disconnect and isolate battery negative cable.
2. Remove the outer rear lamp unit from the vehicle. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/LAMP, Tail Stop Turn - Removal) .
3. Firmly grasp the bulb socket (1 or 2) on the back of the outer rear lamp unit housing and rotate it counterclockwise about 30 degrees to unlock it.
4. Pull the socket and bulb straight out of the lamp.
5. Pull the base of the bulb straight out of the socket.



With LED Lighting

INNER LAMP

NOTE:

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

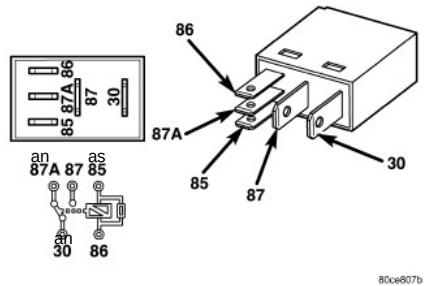
DESCRIPTION

Vehicles equipped with an optional trailer tow preparation package have three trailer tow relays, one each for the trailer tow stop/turn right and left and one for the trailer park lamps. The trailer tow relays are conventional International Standards Organization (ISO) micro relays. Relays conforming to the ISO specifications have common physical dimensions, current capacities, terminal patterns, and terminal functions. Each relay is contained within a small, rectangular, molded plastic housing and is connected to all of the required inputs and outputs through five integral male spade-type terminals that extend from the relay base plate.



The trailer tow relays are included with the trailer tow preparation wire harness that is shipped loose in the glove box for customer or dealer installation at the rear of the vehicle. The relays are located behind the rear fascia and below the rear bumper reinforcement. Each relay and connector is wrapped within an isolator envelope for sound deadening and anti-rattle protection. Refer to the appropriate wiring information for specific relay cavity assignment information.

Any of the trailer tow relays cannot be adjusted or repaired and, if ineffective or damaged, the affected unit must be replaced.

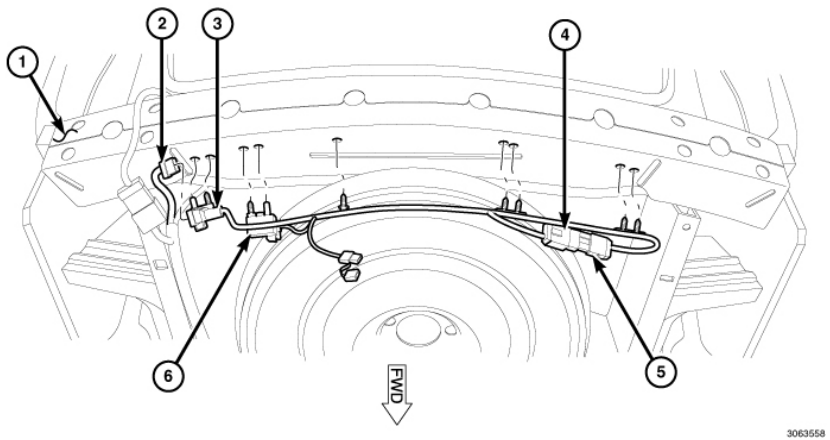
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure



NOTE: There are three relays included with the trailer tow preparation wiring kit. They are: the trailer tow right stop/turn relay (4), the trailer tow left stop/turn relay (5) and the trailer tow park lamps relay (6). The service procedures for all three relays are the same.

1. Align the terminals of the trailer tow right stop/turn relay (4), the trailer tow left stop/turn relay (5) or the trailer tow park lamps relay (6) with the terminal receptacles of the trailer tow wire harness (3) relay connector secured to the underside of the rear bumper reinforcement (1).
2. Firmly and evenly push the relay into the connector until it is fully seated.
3. Reinstall the rear fascia onto the vehicle. (Refer to 13 - Frame and Bumpers/Bumpers/FASCIA, Rear - Installation) .
4. Reconnect the battery negative cable.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The trailer tow relays are electromechanical switches that use a low current input from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) to the tail lamps to control a high current output to either the trailer park lamps or the right or left trailer brake and turn signal lamps. Within each relay are an electromagnetic coil, a movable contact and two fixed contact points. A resistor is connected in parallel with the coil, and helps to dissipate voltage spikes and electromagnetic interference that can be generated as the field of the relay coil collapses.

The movable common supply contact point is held against the fixed normally closed contact point by spring pressure. When the relay coil is energized, an electromagnetic field is produced by the coil windings. This field draws the movable contact away from the normally closed contact, and holds it against the normally open contact. When the relay coil is de-energized, spring pressure returns the movable contact back against the normally closed contact.

The inputs and outputs of the trailer tow relays include:

- **Common Supply Terminal (30)** - The common feed terminal of both the left and right trailer tow stop/turn relays is connected to their respective left or right trailer tow stop/turn signal pins of the 4-way trailer tow connector at all times. The common feed terminal of the trailer tow park lamps relay is connected to the trailer tow park lamps pin of the 4-way trailer tow connector at all times.
- **Coil Ground Terminal (85)** - The coil ground terminal of both the left and right trailer tow stop/turn relays is connected to a fused B(+) circuit at all times. The coil ground terminal of the trailer tow park lamps relay is also connected to a fused B(+) circuit at all times.
- **Coil Battery Terminal (86)** - The coil battery terminal of both the left and right trailer tow stop/turn relays is connected to their respective left or right trailer tow stop/turn relay control circuits from the BCM at all times. The coil battery terminal of the trailer tow park lamps relay is connected to the trailer tow park lamps relay control from the BCM at all times.
- **Normally Open Terminal (87)** - The normally open terminal of both the left and right trailer tow stop/turn relays is connected to a fused B(+) circuit at all times. The normally open terminal of the trailer tow park lamps relay is also connected to a fused B(+) circuit at all times.
- **Normally Closed Terminal (87A)** - The normally closed terminal of all three trailer tow relays are connected to their respective common supply (30) terminals whenever the relay is de-energized. The normally closed terminals of the trailer tow relays are not connected to any circuit in this application.

The trailer tow relays and the hard wired circuits for the relays may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between other modules and devices that provide some features of the trailer tow stop/turn and park lamps lighting system. The most reliable, efficient, and accurate means to diagnose the electronic controls and communication related to trailer tow stop/turn and park lamps lighting operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

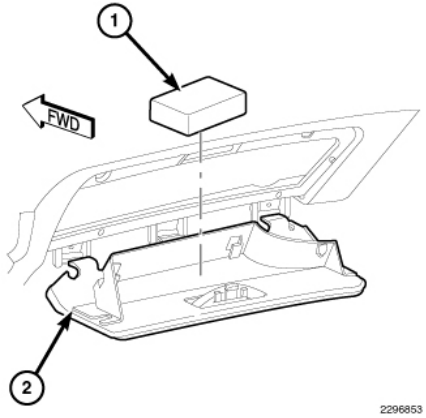
DESCRIPTION

Vehicles equipped with an optional Trailer Tow Preparation package have a trailer tow wiring harness and an instruction sheet (1) that are placed in the glove box (2) of the vehicle when it is shipped from the factory. This package also includes relays to isolate the trailer lighting from the vehicle lighting and a four-way trailer tow wiring connector that are all concealed behind the rear bumper fascia after installation is complete.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The trailer tow preparation wiring harness is connected to the body wire harness near the left side of the spare tire, just forward of the rear bumper reinforcement. After installation is complete, a trailer tow right stop/turn relay, a trailer tow left stop/turn relay and a trailer tow park lamps relay are secured to the trailer tow harness on the underside of the rear bumper reinforcement behind the rear fascia. The four-way trailer tow connector is located near the center of the rear fascia.

Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds. Also refer to the Instruction Sheet packaged with the harness for additional details.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The turn signal cancel cam is concealed within the clockspring case on the steering column. The turn signal cancel cam consists of integral eccentrics on the outer circumference of the molded plastic clockspring rotor. The clockspring mechanism provides turn signal cancellation as well as a constant electrical connection between the horn switch, driver airbag, speed control switches, Electronic Vehicle Information Center (EVIC) switches and remote radio switches on the steering wheel and the instrument panel wire harness on the steering column. The housing of the clockspring is secured to the steering column and remains stationary. The rotor of the clockspring, including the turn signal cancel cam lobes rotate with the steering wheel.

The turn signal cancel cam is serviced as a unit with the clockspring and cannot be repaired. If ineffective or damaged, the entire clockspring unit must be replaced. (Refer to 10 - Restraints/CLOCKSPRING - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

When the multi-function switch control stalk is moved to a latched turn signal ON position, a turn signal cancel actuator is extended from the inside surface of the switch housing through a small rectangular opening on the left side of the clockspring case toward the turn signal cancel cam. As the steering wheel is rotated to complete the turn, one of the cam eccentrics will contact the actuator, automatically cancelling the turn signal event and releasing the latched multi-function switch control stalk to the neutral or OFF position.

WARNING

WARNING: **To avoid serious or fatal injury, eye protection should be used when servicing any glass components.**

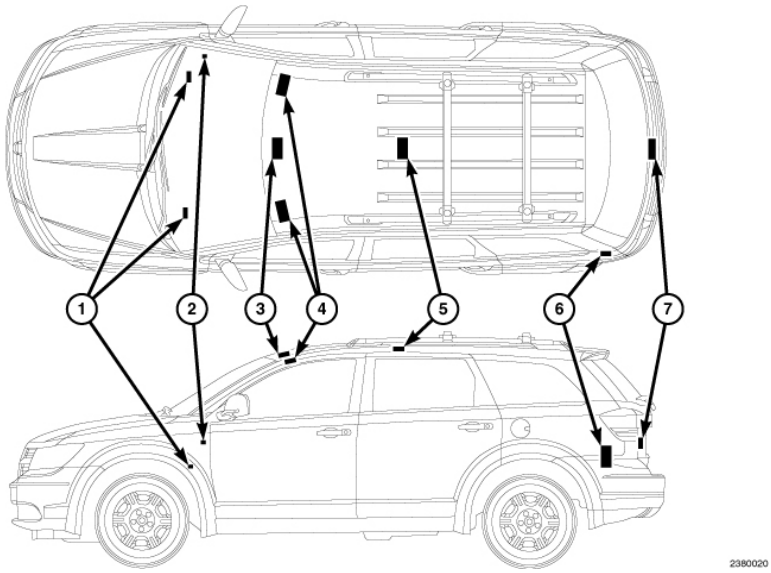
CAUTION: **Do not contaminate the glass of halogen bulbs with fingerprints or allow contact with other possibly oily surfaces. Reduced bulb life will result.**

CAUTION: **Do not use bulbs with higher candle power than indicated in the Bulb Application table. . In addition, do not use fuses, circuit breakers or relays having greater amperage value than indicated on the fuse panel or in the Owner's Manual. Damage to lamps, lenses, wiring and other related electrical components can result.**

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION



The interior lighting system for this vehicle includes lighting on two separate circuits: the dome/courtesy lamp circuit and the panel lamps dimmer circuit. The lamps on the dome/courtesy circuit include:

- **Center Bezel Lamp** - A standard center bezel lamp with a replaceable incandescent bulb is located on the underside of an opening in the instrument panel center bezel to illuminate the center console forward storage bin and is supplied voltage by the park lamp circuit to illuminate whenever the exterior lighting is turned ON.
- **Center Floor Console Cup Holder Lamp** - The cup holders in the center floor console include a standard equipment light pipe around their inside perimeter illuminated by an LED lamp unit to assist visibility at night. This lamp is controlled by the panel lamps dimmer circuit and illuminates whenever the exterior lighting is turned ON.
- **Front Dome/Reading Lamps (3)** - The standard front dome/reading lamp is centered right to left in the headliner near the windshield header, includes two bulbs and is switched by the door ajar switches or the interior lighting control sleeve of the left multi-function switch. This lamp also has two integral push button actuated switches. In vehicles with an optional overhead console these lamps are replaced by two incandescent dome/reading lamps mounted in the same location, with includes integral switches that are actuated by depressing the lamp lens. In vehicles with an optional Light Emitting Diode (LED) lighting package, with or without an overhead console, the two incandescent dome/reading lamps are replaced by two articulating eyeball LED lamp units that also include integral switches that are actuated by depressing the lamp lens.
- **Front Door Map Pocket Lamps** - Front door trim panel map pockets on some models include an LED lamp unit to assist visibility at night. These lamps are controlled by the panel lamps dimmer circuit and illuminate whenever the exterior lighting is turned ON.
- **Glove Box Lamp (2)** - A standard glove box lamp with an integral plunger-actuated switch is located at the upper outboard corner of the instrument panel lower glove box opening and illuminates whenever the glove box door is opened.
- **Instrument Panel Courtesy Lamps (1)** - Vehicles equipped with an optional LED lighting package have an LED courtesy lamp unit beneath each end of the instrument panel near the lower instrument panel reinforcement.
- **Liftgate Courtesy Lamp (7)** - A standard liftgate courtesy lamp is located in the center of the lower liftgate trim panel and is activated automatically whenever the liftgate is opened to illuminate the rear cargo area of the vehicle.
- **Rear Dome/Reading Lamps (5)** - The standard rear dome/reading lamp includes a single bulb and a switch that is actuated by depressing the lamp lens. In vehicles with an optional LED lighting package, the incandescent lamp is replaced by a lamp that includes a fixed auxiliary LED dome lamp and two articulating eyeball LED lamp units that also include integral switches that are actuated by depressing the lamp lens. Each available rear dome/reading lamp is located in the center of the headliner between the second and third row seating.
- **Rechargeable Flashlight (6)** - An optional, removable twin-LED flashlight powered by rechargeable lithium batteries is mounted in a bezel/charging station located in the left quarter trim panel near the D-pillar in the cargo area of the vehicle.
- **Vanity Lamps (4)** - Optional single-intensity vanity lamps are located on both sides of a covered mirror on both the right and left sun visors. These lamps are controlled by an integral vanity mirror cover-actuated switch.

Most controls on the instrument panel and elsewhere in the interior of the vehicle are illuminated by the panel lamps dimmer circuit for night visibility. Most have miniature incandescent bulbs, Light-Emitting Diode (LED) units or a combination of the two lighting types that are soldered to internal circuit boards and are not serviceable. Only the automatic transmission gearshift indicator incandescent bulb is available for individual service replacement.

Other components of the interior lighting system for this vehicle include:

- **Body Control Module** - The Body Control Module (BCM) (also known as the Common Body Controller/CBC) is located beneath the instrument panel on the passenger side of the vehicle. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Body Control - Description) .
- **Dimmer Module** - A dimmer module is located on the left side of the instrument panel, below and outboard of the steering column just inboard from the headlamp switch. The dimmer module features a vertical thumbwheel for selecting the panel lamps dimming level, a PARADE mode to illuminate all Vacuum Fluorescent Display (VFD) units at full brightness for visibility when driving in daylight with the exterior lighting turned ON. There are also detent positions to turn ON all interior courtesy lighting, and a DEFEAT position that overrides door ajar switch control of interior lighting.
- **Door Ajar Switches** - A door ajar switch is integral to the door latch mechanism of each front and rear door.
- **Liftgate Ajar Switch** - A liftgate ajar switch is integral to the latch mechanism of the liftgate.

Hard wired circuitry connects the interior lighting system components to the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system and to the interior lighting components through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

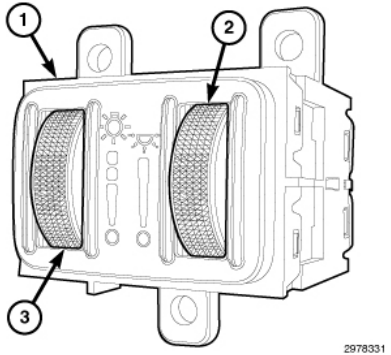
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

This vehicle has a separate dimmer module (1) that is located on the instrument panel, in a mounting hole inboard of the headlamp switch mounting hole, outboard of the steering column. The standard dimmer module features a single thumbwheel (3) for panel lamps dimming and interior lighting control. There are also two optional switches with a second thumbwheel (2). The second thumbwheel is used for ambient (also known as halo) lighting control in vehicles with the ambient lighting option, or for headlamp leveling control in vehicles manufactured for certain markets where headlamp leveling is required.

The dimmer module is constructed of molded plastic. The thumbwheel is molded plastic and knurled around its circumference to ease operator control. The dimmer module face plate is labeled with graphics and International Control and Display Symbol icons to clearly identify the functions of the thumbwheel or optional thumbwheels.



The dimmer module housing is secured within the mounting hole of the instrument panel by three screws, two on the top and one on the bottom. The back of the dimmer module housing has an integral connector receptacle containing terminal pins that connect the module to the vehicle electrical system through a dedicated take out and connector of the instrument panel wire harness. Panel dimmer controlled Light Emitting Diode (LED) units soldered to the circuit board within the module provide back lighting for visibility at night, but are not serviceable.

The dimmer module cannot be repaired and, if ineffective or damaged, it must be replaced.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The dimmer module uses a single resistor multiplexed output for each switch thumbwheel to control the many functions and features it provides. The switch receives a clean ground from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) on a multifunction switch MUX return circuit. It then provides outputs to the BCM on a panel lamps dimmer signal circuit to control panel dimmer and interior lighting functions, or on a dimmer environmental lighting circuit to control ambient (halo) lighting functions.

On vehicles equipped with a remote manual headlamp leveling system, the dimming module also receives a battery voltage input on a park/tail/running lamps feed circuit whenever the exterior lighting is turned ON. It then provides outputs to the BCM on a headlamp leveling switch to module signal circuit to control the headlamp leveling function.

The dimmer module illumination circuit receives a path to ground at all times through an instrument panel ground circuit. The illumination level is controlled by a Pulse-Width Modulated (PWM) output received from the BCM on a panel lamps driver circuit. The BCM controls this output based upon the panel lamps dimmer signal circuit input from the dimmer module.

The dimmer module operates as follows:

- **Ambient (Halo) Lighting Control** - On vehicles so equipped, the right thumbwheel on the dimmer module is rotated to the ambient DEFEAT or one of the six ambient dimmer detent positions to control the ambient (halo) lighting level. The dimmer module provides the appropriate resistor multiplexed output to the BCM over the dimmer environmental lighting circuit. The BCM reads and responds to this input by providing the appropriate control outputs through internal HSDs over the liftgate courtesy feeds driver circuit.
- **Headlamp Leveling Control** - On vehicles so equipped, the right thumbwheel on the dimmer module is rotated to the 0, 1 or 2 detent positions to provide the appropriate resistor multiplexed output to the BCM over the headlamp leveling switch to module signal circuit. The BCM reads and responds to this input by providing the appropriate control outputs to the headlamp leveling motors.
- **Interior Lighting Control** - The left thumbwheel on the dimmer module is rotated to the dome DEFEAT, dome ON, PARADE mode, or one of the six panel dimmer detent positions to control the interior courtesy/dome and panel lamps. The dimmer module provides the appropriate resistor multiplexed output to the BCM over the panel lamps dimmer signal circuit. The BCM reads and responds to this input by providing the appropriate control outputs through internal HSDs over the courtesy lamps, panel lamps and reading lamps driver circuits, and by sending appropriate electronic **dimming level** messages to other electronic modules over the CAN data bus.

The dimmer module as well as the hard wired inputs and outputs of the module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Disconnect and isolate the battery negative cable.
2. Remove the steering column opening cover and knee blocker unit from the instrument panel. (Refer to 23 - Body/Instrument Panel/COVER, Steering Column Opening - Removal) .
3. Reach through the steering column opening of the instrument panel to access and disconnect the instrument panel wire harness connector from the connector receptacle (2) of the dimmer module (3).
4. Remove the three screws (4) that secure the dimmer module to the back of the instrument panel base trim (1).
5. Remove the dimmer module from the instrument panel.

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Disconnect and isolate the battery negative cable.
2. Open the glove box door.
3. Reach through and behind the upper outboard corner of instrument panel glove box opening to access and depress the retaining latch on either side of the glove box lamp and switch unit (1).
4. While holding the retaining latch depressed, push the glove box lamp and switch unit out through the mounting hole in the face of the instrument panel.
5. Disconnect the wire harness connector from the glove box lamp and switch.
6. Remove the lamp and switch unit from the instrument panel.

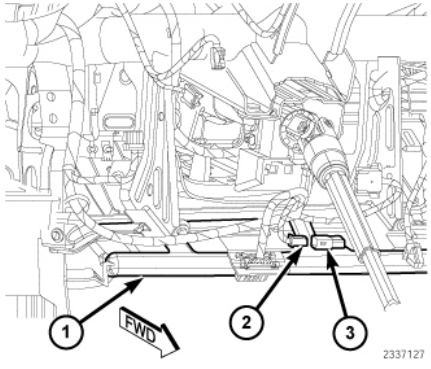
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: The Light Emitting Diode (LED) and printed circuit board for these lamps are serviced only as a unit with the courtesy lamp assembly. If any part of these lamps is damaged or ineffective, the entire lamp assembly must be replaced.



1. Position the courtesy lamp (3) under the lower edge of the instrument panel steering column opening (driver side) or glove box opening (passenger side) lower reinforcement (1).
2. Reconnect the instrument panel wire harness connector (2) to the connector receptacle integral to the courtesy lamp.
3. Align the push-in plastic retainer on the underside of the courtesy lamp with the mounting hole in the instrument panel lower reinforcement.
4. Using hand pressure, press the courtesy lamp downward firmly and evenly until the push-in plastic retainer is fully engaged in the mounting hole.
5. If the vehicle is so equipped, reinstall the closeout panel under the driver or passenger side of the instrument panel. (Refer to 23 - Body/Instrument Panel/PANEL, Silencer - Installation) .
6. Reconnect the battery negative cable.

OPERATION

The lamps of the interior lighting system can be divided into general classifications based upon the circuit that controls their operation: The courtesy lamp circuit, the reading lamps circuit and the panel lamps dimmer circuit. The center bezel lamp is actually controlled by a park lamps output of the Body Control Module (BCM) (also known as the Common Body Controller/CBC), which energizes this circuit at a fixed intensity whenever the exterior lighting is illuminated.

Following are paragraphs that briefly describe the operation of the courtesy lamps, reading lamps and panel lamps dimmer interior lighting circuits. The optional rechargeable flashlight, the cup holder lamp and the automatic transmission gear selector lamp are controlled by an output from the BCM, which energizes these circuits whenever it detects that the engine is running.

The lamps and the hard wired circuits between components related to the interior lighting system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the interior lighting system or the electronic controls or communication between modules and other devices that provide some features of the interior lighting system. The most reliable, efficient, and accurate means to diagnose the interior lighting system or the electronic controls and communication related to interior lighting system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

COURTESY LAMP CIRCUIT

The courtesy lamp circuit may include the courtesy lamps below each outboard end of the instrument panel and, depending upon the selected vehicle options may include either the dome or map and reading lamps located in the overhead console near the windshield and in the headliner over the second and optional third row seating positions, the liftgate lamp located near the center of the liftgate trim panel, the glove box lamp in the top of the glove box opening in the instrument panel and the vanity lamps located in the sun visors.

The lamps in the courtesy lamp circuit are provided with a path to ground at all times. The Body Control Module (BCM) (also known as the Common Body Controller/CBC) controls the output of battery voltage for the courtesy lamps in this circuit based upon hard wired inputs from the dimmer module and electronic message inputs from the ignition switch (also known as the Keyless Ignition Node/KIN) and the Radio Frequency (RF) Hub.

After all of the ajar switch inputs to the BCM transition to open, the BCM will keep the courtesy lamps illuminated for about 30 seconds, then fade the lamps to OFF (theater dimming) over about 3 seconds. The BCM also provides courtesy lamp operation based upon a resistor multiplexed input from the interior lighting thumbwheel of the dimmer module, and provides an Illuminated Entry feature in response to certain electronic **ignition switch status** message inputs received from the KIN, the RF Hub and the Occupant Restraint Controller (ORC) over the CAN data bus. A courtesy lamp DEFEAT mode input based upon a resistor multiplexed input from the interior lighting thumbwheel of the dimmer module thumbwheel will cause the BCM to override normal courtesy lamp operation.

The BCM provides a battery saver (load shedding) feature for all courtesy lamps, which will automatically turn these lamps OFF if they are left ON for more than about 10 minutes after the electronic **ignition switch status** message transitions to OFF. If any courtesy lamp input is received subsequent to a 10 minute load shed and prior to a new ignition cycle, the courtesy lamps will turn OFF after 90 seconds.

READING LAMP CIRCUIT

For those lamps on the courtesy lamp circuit with independent switching such as the reading lamps, the optional vanity lamps and the glove box lamp, the BCM also provides a battery voltage output to those switches through a separate reading lamp circuit. The BCM provides a battery saver (load shedding) feature for the reading lamp circuit as well as the courtesy lamp circuit, which will automatically turn these lamps OFF if they are left ON for more than about 10 minutes after the electronic **ignition switch status** message transitions to OFF. If any reading lamp input is received subsequent to a 10 minute load shed and prior to a new ignition cycle, the courtesy lamps will turn OFF after 90 seconds.

PANEL LAMPS DIMMER CIRCUIT

The panel lamps dimmer circuit actually includes several circuits. These circuits control the back lighting illumination and dimming level of the headlamp switch, the dimmer module, the automatic transmission gear selector bezel lamp, the front door map pocket lamps, as well as the center floor console cup holder and forward storage compartment lamps. All lamps in the panel lamps dimmer circuits are provided a path to ground at all times through a hard wired ground circuit. These lamps are illuminated by a 12-volt Pulse Width Modulated (PWM) output of the BCM through several panel lamps dimmer circuits.

This shared PWM output synchronizes the selected illumination intensity level of all the lamps in the panel lamps dimmer circuits. The BCM uses hard wired resistor multiplexed inputs from the rotary exterior lighting control knob of the headlamp switch to determine when the exterior lighting is turned ON and from the thumbwheel of the dimmer module to determine the dimming level selection. Then the BCM provides the appropriate PWM outputs through the panel lamps dimmer circuits as well as electronic **dimming level** messages over the CAN data bus to other electronic modules in the vehicle.

The Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and the Integrated Center Stack (ICS) use the electronic **dimming level** messages to control the illumination intensity of their own back lighting, controls and display units. In addition, when the interior lighting thumbwheel of the dimmer module is moved to the PARADE (or funeral) mode detent position, all of the electronic display units are illuminated at their full intensity levels for increased visibility when the vehicle is driven during daylight hours with the exterior lighting turned ON. The PARADE mode has no effect on the illumination intensity of incandescent panel lamps.

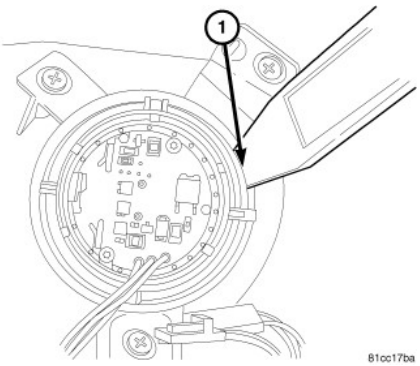
LIGHT EMITTING DIODE UNIT

Labor Operations: Click to display a list of Labor Operations associated with this procedure

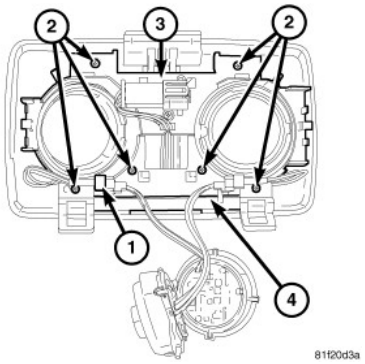
NOTE: Each Light Emitting Diode (LED) dome/reading lamp contains two articulating eyeball-type LED pod units with integral lens-actuated switches and printed circuit boards that are available for separate service replacement. The rear LED dome/reading lamp also has a fixed auxiliary LED and printed circuit board unit which is also available for separate service replacement.

ARTICULATED EYEBALL POD UNIT



1. On rear LED dome/reading lamp units only, from the top of the lamp housing, reconnect the pod pigtail wire connector to the fixed auxiliary LED lamp printed circuit board in the center of the lamp.
2. Align the LED lamp pod (1) with the receptacle within the dome/reading lamp housing.
3. Engage the pivot pin on one side of the pod with the pivot socket on one side of the pod receptacle.
4. Using a trim stick or another suitable wide flat-bladed tool, gently pry the receptacle outward far enough to engage the pivot pin on the other side of the pod with the other pivot socket.
5. Using a trim stick or equivalent, flex the housing at point (1) and install lamp pod.
6. Reinstall the LED dome/reading lamp unit. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Interior/LAMP, Dome - Installation) .
7. Reconnect the battery negative cable.

FIXED AUXILIARY LED AND CIRCUIT BOARD UNIT



1. Position the auxiliary LED and circuit board unit (4) into the lamp housing.
2. Install and tighten the six screws (2) that secure the printed circuit board to the lamp housing. Tighten the screws securely.
3. Reconnect the lamp wiring to the auxiliary LED wiring connector (3).
4. Reinstall and reconnect (1) the two articulated eyeball LED pods into the lamp housing.
5. Reinstall the rear LED dome/reading lamp unit. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Interior/LAMP, Dome - Installation) .

6. Reconnect the battery negative cable.

DESCRIPTION

An optional removable and rechargeable flashlight (3) is encased within a molded plastic housing, which is secured within a bezel/charging station (2) at the back of the left quarter inner trim panel (1) by two tabs on the end opposite the clear flashlight lens and a push-push type latch mechanism. The flashlight is powered by a rechargeable and replaceable lithium battery. A momentary switch on the flashlight electronic circuit board is actuated by a plastic push button located on the side of the flashlight housing. When the flashlight is turned ON it illuminates two clear Light Emitting Diode (LED) units to create a wide and bright light beam. A red LED unit on the side of the flashlight housing behind the push button illuminates as the battery becomes discharged to indicate that the unit requires recharging.

The bezel/charging station unit, the flashlight battery and the flashlight unit are each available for separate service replacement. If any other component of the flashlight or bezel/charging station are damaged or ineffective, the complete flashlight unit or bezel/charging station unit must be replaced.

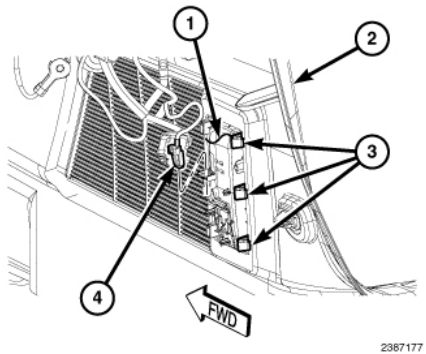
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Align the bezel/charging station (1) with the mounting hole near the rear of the left quarter trim panel (2).
2. Using hand pressure, push the bezel/charging station into the mounting hole firmly and evenly until all 6 of the spring clip retainers (3) snap into place on the back side of the trim panel.
3. Reconnect the body wire harness connector (4) to the connector receptacle on the back of the bezel/charging station.
4. Reinstall the left quarter trim panel. (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Installation) .
5. Reconnect the battery negative cable.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The rechargeable lithium battery within the flashlight automatically recharges while the flashlight is nested in its receptacle within the bezel charging station and the engine is running. The flashlight has a pair of electrical contacts that mate with contacts within the charging station that provide a source of recharging current. The red Light Emitting Diode (LED) unit on the side of the flashlight behind the ON-OFF push button illuminates when the charge of the flashlight battery is becoming depleted.

The flashlight is removed from the bezel/charging station by pushing it momentarily at the depression marked **PUSH** on the flashlight housing, then releasing it and swinging it downward far enough to disengage two slots on the lower end of the flashlight from two tabs within the charging station. When the flashlight is removed from its receptacle in the bezel/charging station, it can be used as an auxiliary light source in emergencies or other situations where a portable light source is required. The flashlight is turned ON or OFF by momentarily depressing and releasing the ON-OFF push button on the side of the flashlight housing. Reverse the removal procedure to restore the flashlight to the bezel/charging station and to recharge the flashlight battery.

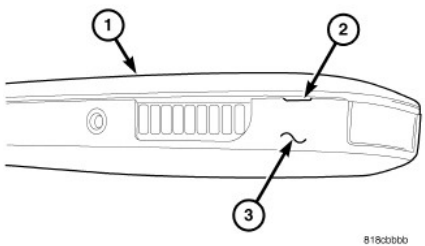
STANDARD PROCEDURE - FLASHLIGHT BATTERY REPLACEMENT

1. Insert a small screwdriver or another suitable tool into each of the two notches (2) between the upper (1) and lower (3) case halves of the flashlight and use a twisting action to separate the case.



2. Remove the lower case (4) from the upper case (3) and set it aside.
3. Lightly lift the latch tab (2) at the back of the upper case and slide the battery (1) rearward far enough to remove it from the case.
4. Install the new battery by sliding it between the latch tab and the case until it is engaged by the latch tab. The battery **must** be installed with the positive (**+**) terminal oriented toward the upper case (3).

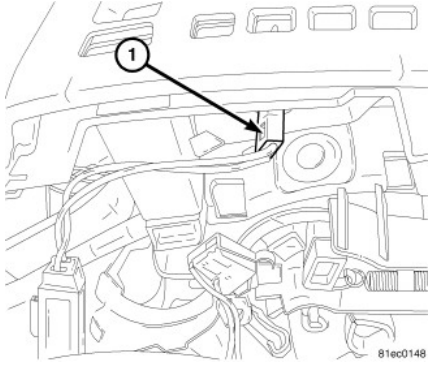
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **Always use the correct bulb size and type for replacement. An incorrect bulb size or type may overheat and cause damage to the lamp, the socket or the lamp wiring.**



1. Align the base of the bulb with the socket (1) on the side of the gear selector housing.
2. Push the bulb straight into the socket until the base is firmly seated.
3. Align the socket and bulb with the keyed opening in the side of the gear selector housing.
4. Insert the bulb and socket into the housing until the socket is firmly seated.
5. Rotate the socket clockwise about 30 degrees to lock it into place.
6. Reinstall the center floor console. (Refer to 23 - Body/Interior/CONSOLE, Center - Installation) .
7. Reconnect the battery negative cable.

HEADLAMP

An electrically operated headlamp washer system is optional factory-installed equipment on this vehicle when it is manufactured for certain export markets. The headlamp washer system includes the following major components, which are described in further detail elsewhere in this service information:

- **Body Control Module** - The Body Control Module (BCM) (also known as the Common Body Controller/CBC) is located beneath the instrument panel on the passenger side of the vehicle. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Body Control - Description) .
- **Headlamp Washer Nozzle** - A headlamp washer nozzle is secured to the front fascia beneath each front lamp unit.
- **Headlamp Washer Pump/Motor** - The electric headlamp washer pump/motor unit is located in a dedicated hole on the rearward facing side of the washer reservoir, on the left side of the cooling module in the engine compartment. This high pressure pump is located above and to the left of the reversible front and rear washer pump/motor unit on the reservoir.
- **Headlamp Washer Plumbing** - The plumbing for the headlamp washer system consists of large diameter rubber hoses and molded plastic fittings. The plumbing is routed to the washer nozzles on the front fascia from the washer reservoir. The connections at the headlamp washer pump and the two headlamp washer nozzles feature unique quick-connect fittings.
- **Multifunction Switch (6)** - The multifunction switch is located on the steering column, just below the steering wheel. Only the switch control stalk extending from the left side of the steering column is visible, while the remainder of the switch is concealed beneath the steering column shrouds. The multifunction switch provides all of the driver controls for both the front and rear wiper and washer systems.
- **Steering Angle Sensor** - The Steering Angle Sensor (SAS) is integral to the clockspring. The SAS is a Local Interface Network (LIN) master node and a gateway to the Controller Area Network (CAN) data bus. (Refer to 05 - Brakes/Electrical/SENSOR, Steering Wheel Angle - Description) .
- **Steering Control Module** - The Steering Control Module (SCM) is located within the multifunction switch housing on the top of the steering column, just below the steering wheel. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Steering Column - Description) .
- **Washer Reservoir** - A unique washer reservoir is used on vehicles with the optional headlamp washer system, which has dedicated provisions for the headlamp washer pump and plumbing. This reservoir is mounted in the same location and using the same mounting hardware as is used for vehicles without the headlamp washers. The reservoir is located on the left side of the cooling module in the engine compartment.

Hard wired circuitry connects the headlamp washer system components to the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system and to the headlamp washer system components through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin out and location views for the various wire harness connectors, splices and grounds.

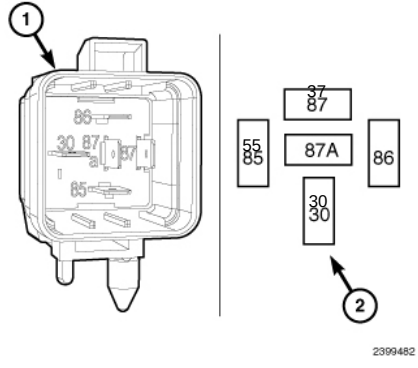
DESCRIPTION

The headlamp washer relay (1) is a conventional International Standards Organization (ISO) skirted relay. Relays conforming to the ISO specifications have common physical dimensions, current capacities, terminal patterns (2), and terminal functions. This relay is contained within a small, rectangular, molded plastic housing and is connected to all of the required inputs and outputs through five integral male spade-type terminals that extend from the relay base plate.

The headlamp washer relay is located in a dedicated connector on a take out of the Front End Module (FEM) wire harness, and is secured to the radiator closure panel to the left of the washer reservoir in front of the engine compartment Power Distribution Center (PDC), near the battery. The headlamp washer relay cannot be adjusted or repaired and, if ineffective or damaged, the unit must be replaced.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The headlamp washer relay is an electromechanical switch that uses a low current input from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) to control a high current output to the headlamp washer pump/motor unit. The movable common feed contact point is held against the fixed normally closed contact point by spring pressure. When the relay coil is energized, an electromagnetic field is produced by the coil windings. This electromagnetic field draws the movable relay contact point away from the fixed normally closed contact point, and holds it against the fixed normally open contact point. When the relay coil is de-energized, spring pressure returns the movable contact point back against the fixed normally closed contact point. A resistor is connected in parallel with the relay coil in the relay, and helps to dissipate voltage spikes and electromagnetic interference that can be generated as the electromagnetic field of the relay coil collapses.

The headlamp washer relay terminals are connected to the vehicle electrical system through a dedicated take out and connector of the Front End Module (FEM) wire harness. The inputs and outputs of the headlamp washer relay include:

- **Common Feed Terminal** - The common feed terminal (30) is connected to battery current on a fused B(+) circuit from a fuse in the engine compartment Power Distribution Center (PDC) at all times.
- **Coil Ground Terminal** - The coil ground terminal (85) is connected to battery current on a fused run relay output circuit from a fuse in the engine compartment PDC at all times. This circuit is energized by the run relay only while the engine is running.
- **Coil Battery Terminal** - The coil battery terminal (86) is connected to a low side driver output from the BCM on a headlamp washer relay control circuit. The BCM controls headlamp washer system operation through this relay connection.
- **Normally Open Terminal** - The normally open terminal (87) is connected through a headlamp washer relay output circuit to the headlamp washer pump/motor unit at all times. When the relay is energized, the normally open terminal of the relay is connected to battery current from the fuse in the engine compartment PDC.
- **Normally Closed Terminal** - The normally closed terminal (87A) is not connected to any circuit in this application, but will have battery current present whenever the headlamp washer relay coil is not energized.

The headlamp washer relay as well as the hard wired inputs and outputs of the relay may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between modules and other devices that provide some features of the headlamp washer system. The most reliable, efficient and accurate means to diagnose the headlamp washer relay or the electronic controls and communication related to headlamp washer system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

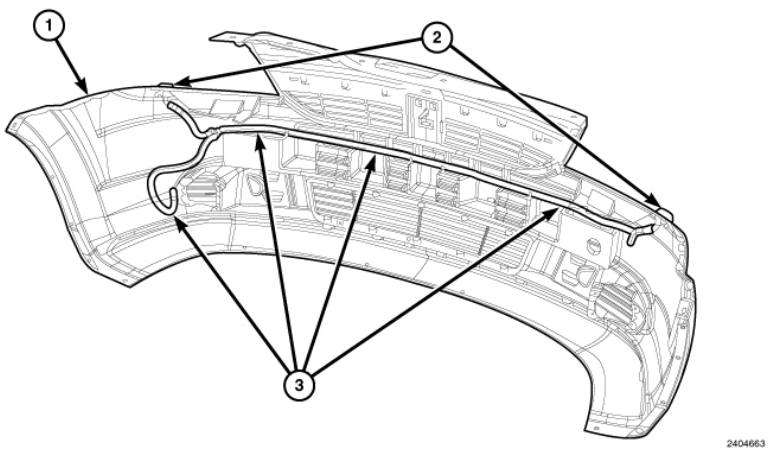
HEADLAMP



The headlamp washer system plumbing consists of a large diameter high pressure rubber hose (3) that is routed from the outlet nipple of the headlamp washer pump/motor unit on the washer reservoir to the barbed nipple of a tee fitting with an integral check valve located near the left headlamp washer nozzle on the back side of the front fascia (1). The other two barbed nipples of the tee fitting are connected to one short and one long length of hose that each terminate at a headlamp washer nozzle (2) behind the fascia and below the two front lamp units. The hose is secured and routed from left to right behind the fascia and above the fascia reinforcement by several routing clips. The hose connections at the nozzles and the washer pump are secured using molded plastic quick-connect fittings.

The headlamp washer hose is serviced only as a complete unit. The molded plastic washer hose fittings and check valve cannot be repaired. If these fittings or the check valve are ineffective or damaged, the entire headlamp washer hose unit must be replaced.

HEADLAMP

Washer fluid in the washer reservoir is pressurized and fed by the headlamp washer pump/motor unit through the headlamp washer system plumbing and fittings to the two headlamp washer nozzles. Whenever routing the washer plumbing, it must be routed away from hot, sharp, or moving parts; and, sharp bends that might pinch the plumbing must be avoided.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

HEADLAMP

The headlamp washer system is designed to provide the vehicle operator with a convenient, safe, and reliable means of maintaining headlamp lighting performance. The various components of this system are designed to convert electrical energy produced by the vehicle electrical system into the hydraulic action of the washer system to apply washer fluid stored in an on-board reservoir to the lenses of the two front lamp units, removing excess accumulations of snow, ice, bugs, mud or other minor debris from the front lamps that might be encountered while driving the vehicle under numerous types of inclement operating conditions.

The vehicle operator initiates the headlamp washer system function using the control knob on the end of the multifunction switch control stalk that extends from the left side of the steering column, just below the steering wheel. While the headlamps are turned On and the engine is running, pushing the knob on the end of the control stalk towards the steering column beyond the actuation point for more than about 100 milliseconds (0.10 second) activates the headlamp washer pump/motor in combination with the front washer pump/motor. When the headlamp washer pump/motor unit is energized, hydraulic pressure builds within the headlamp washer system plumbing against the pressure of the control valve in each headlamp washer nozzle. Sufficient pressure causes the headlamp washer nozzles to dispense high pressure washer fluid onto the lenses of both front lamp units for about 1600 milliseconds (1.6 seconds).

Depressing the control knob towards the steering column actuates the momentary front washer system switch, which selects the Headlamp Wash mode, depending upon when and how long the switch is held closed. Headlamp washer system operation is completely controlled by the Body Control Module (BCM) (also known as the Common Body Controller/CBC) logic circuits based upon electronic **wash command** message inputs received from the Steering Angle Sensor (SAS) over the Controller Area Network (CAN) data bus. The SAS monitors electronic **wash switch status** and **lighting switch status** message inputs received over the Local Interface Network (LIN) data bus from the Steering Control Module (SCM) (also known as the Steering Column Module/SCM) based upon the multifunction switch positions. The BCM will only allow this system to operate when the engine is running and the headlamp low beams are turned On. The BCM uses a low side driver to energize or de-energize a headlamp washer relay in the Power Distribution Center (PDC) to control the headlamp washer pump/motor unit.

The hard wired circuits and components of the headlamp washer system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the headlamp washer system or the electronic controls or communication between other modules and devices that provide some features of the headlamp washer system. The most reliable, efficient, and accurate means to diagnose the headlamp washer system or the electronic controls and communication related to headlamp washer system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

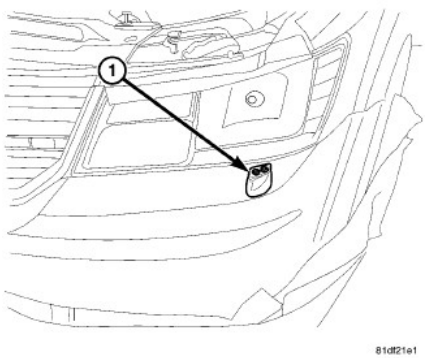
HEADLAMP

Vehicles equipped with the optional headlamp washer system have two fixed headlamp washer nozzles (1), one secured to the front fascia beneath each front lamp unit.



Each nozzle includes two orifices (1) to ensure complete headlamp lens coverage by the fluid streams emitted from the nozzle. The fixed body of the molded plastic nozzle is located below the front fascia. An integral mounting bezel (2) is secured by two integral latch features (3) within the mounting hole in the front fascia. A large diameter high pressure washer fluid supply hose from the dedicated headlamp washer pump/motor unit is routed to the nozzle, where it is secured by a quick connect fitting to the nipple fitting (4) at the base of the nozzle.

The headlamp washer nozzle cannot be adjusted or repaired and, if ineffective or damaged, the entire nozzle and mounting bezel must be replaced with a new unit.

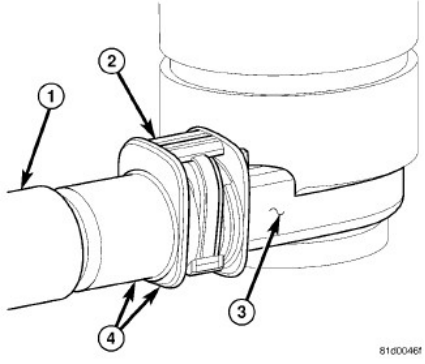
HEADLAMP

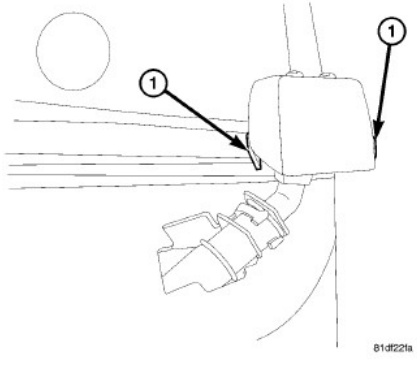
Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **Take proper precautions to ensure there is no cosmetic damage done to the paint finish of the headlamp washer nozzle bezel or the front fascia during the following procedure.**

1. Pull the washer nozzle supply hose (1) quick connect fitting (4) out through the mounting hole of the front fascia far enough to seat the molded plastic lock (2) onto the fitting.
2. Push the quick connect fitting onto the headlamp washer nozzle nipple (3) until it snaps into place with an audible click.



3. Position the headlamp washer nozzle into the mounting hole in the front fascia.
4. Align the washer nozzle bezel with the mounting hole in the front fascia.
5. Using hand pressure, push the bezel down into the fascia mounting hole until both bezel latch features are fully engaged on the back side of the fascia.
6. Reach up behind the front fascia to access and remove the clamp from the washer supply hose.
7. Reinstall the push pin retainers that secure the lower front edge of the front wheel house splash shield. (Refer to 23 - Body/Exterior/SHIELD, Splash - Installation) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

HEADLAMP

When the headlamp washer pump/motor unit is activated, pressure builds within the high pressure hoses to each headlamp washer nozzle. Driven by this pressure, a control valve integral to each nozzle allows a precisely metered quantity of washer fluid to be sprayed in several high pressure streams against the lenses of both front lamp units. When the pressure drops, the control valve closes and the nozzle spray ceases.

The headlamp washer system only operates when the engine is running and the headlamps are turned ON. When those conditions have been met, the headlamp washer system operates whenever the front (windshield) washer system is activated.

HEADLAMP

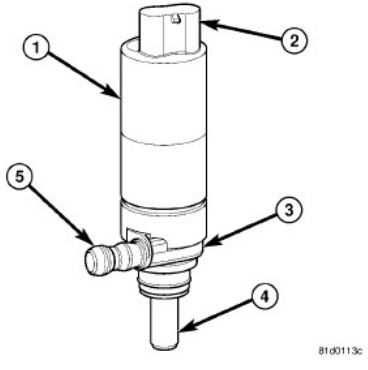
The headlamp washer pump/motor unit (1) of vehicles so equipped is located on the top of a sump area just above and outboard of the reversible front and rear washer pump on the rearward facing side of the washer reservoir, on the upper left corner of the cooling module in the engine compartment. A small permanently lubricated and sealed electric motor is coupled to the rotor-type washer pump.

An inlet nipple (4) on the bottom of the pump housing (3) passes through a rubber grommet seal/filter screen installed in a dedicated mounting hole of the washer reservoir. When the pump is installed in the reservoir the quick connect outlet nipple (5) on the pump housing points toward the left side of the vehicle and connects the unit to the headlamp washer plumbing.



The headlamp washer pump/motor unit is retained on the reservoir by the interference fit between the pump inlet nipple and the grommet seal, which is a light press fit. The top of the washer pump is also secured to the washer reservoir by a light snap fit into a receptacle molded into the reservoir that allows for mounting of the washer pump without the use of fasteners. An integral connector receptacle (2) on the top of the motor housing connects the unit to the vehicle electrical system through a dedicated take out and connector of the Front End Module (FEM) wire harness.

The headlamp washer pump/motor unit cannot be repaired. If ineffective or damaged, the entire headlamp washer pump/motor unit must be replaced. The rubber grommet seal/filter screen is available for separate service replacement.

Fuel Delivery: | **Fuel:**

HEADLAMP

Headlamp washer pump/motor unit operation is completely controlled by the Body Control Module (BCM) (also known as the Common Body Controller/CBC) logic circuits based upon electronic **wash request** and **lighting request** message inputs received from the Steering Angle Sensor (SAS) integral to the clockspring over the Controller Area Network (CAN) data bus. The SAS monitors electronic **washer switch** and **lighting switch** status messages received over the Local Interface Network (LIN) data bus from the Steering Control Module (SCM). The SCM monitors analog and resistor multiplexed inputs from the front washer switch circuitry contained within the multifunction switch to determine the proper washer switch status messages to send.

The headlamp washer relay control coil operates on battery voltage received from the run relay, so it is only functional while the engine is running. In addition, the BCM will only allow the headlamp washers to operate when the headlamps are turned ON. The BCM uses a low side driver to energize or de-energize the headlamp washer relay which, in turn, controls the operation of the headlamp washer pump/motor unit.

The hard wired circuits and components of the headlamp washer pump/motor unit may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the headlamp washer pump/motor or the electronic controls and communication between other modules and devices that provide some features of the headlamp washer system. The most reliable, efficient and accurate means to diagnose the headlamp washer pump/motor unit or the electronic controls and communication related to headlamp washer pump/motor unit operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **It is important to make sure the motor is square to the glass holder (attaching fingers) prior to glass holder attachment, otherwise the glass holder could be installed incorrectly causing poor retention and possible repeat failure.**

1. Position the new mirror glass holder to the mirror assembly.

   NOTE: Position the mirror glass holder so that the moisture drain hole on the mirror glass holder assembly is facing downward.

2. Align the mirror glass holder's attaching fingers to the mirror motor housing.

   NOTE: Ensure that the protective rubber cover of the mirror motor housing is positioned correctly around the bottom of the fingers area.

3. Using one hand, firmly press the mirror glass holder assembly into place while at the same time supporting the housing assembly from the backside with the other hand.

   NOTE: Pressure must be applied equally over the center portion of the mirror to engage the mirror glass holder's attaching fingers to the corresponding fingers on the housing assembly. One or more clicks may be heard when finger engagement takes place.

4. Verify retention of the mirror glass holder assembly by gently pulling outward on the mirror glass holder.

REAR VIEW MIRROR BUTTON

Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: The rear view mirror button is permanently bonded to the inside of the windshield glass. If the button should become separated from the glass, it may be re-bonded using the following procedure. This procedure requires the use of a Rear View Mirror Adhesive kit that is available through Mopar® in single application packages that include a two-part adhesive and an accelerant with applicator.

1. Mark the proper position for the mirror button on the outside of the windshield glass with a wax pencil. The residual adhesive on the inside of the glass from the prior mirror button installation can be used as a guide.
2. Clean the button contact area on the inside of the glass. Use a mild powdered cleanser on a cloth saturated with rubbing alcohol. Finally, clean the glass with a paper towel dampened with alcohol.
3. Sand the bonding surface (the smaller side) of the support button with fine grit-sandpaper. Wipe the button surface clean with a paper towel.
4. Apply accelerant to the bonding surface of the button according to the following instructions:
   - Crush the accelerant vial to saturate the felt applicator.
   - Remove the paper sleeve.
   - Apply accelerant to the bonding surface of the button.
   - Allow the accelerant to dry for five minutes.
   - Do not touch the button bonding surface after the accelerant has been applied.
5. Apply adhesive accelerant to the button contact area on the inside of the windshield glass. Allow the accelerant to dry for one minute. Do not touch the button contact area of the glass after the accelerant has been applied.
6. Install the button according to the following instructions:
   - Apply one drop of adhesive at the center of the button contact area on the inside of the windshield glass.
   - Apply an even coat of adhesive to the bonding surface of the button.
   - Align the button with the marked position on the windshield glass.
   - Press and hold the button in place for at least one minute.

   NOTE: Verify that the mirror button is correctly aligned, because the adhesive will cure rapidly.
7. Allow the adhesive to cure for 8-10 minutes. Remove any excess adhesive with an alcohol-dampened cloth.
8. Allow the adhesive to cure for an additional 8-10 minutes before reinstalling the mirror.

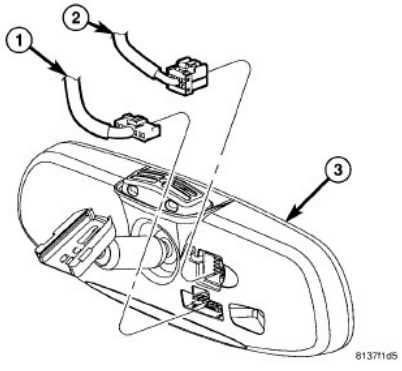
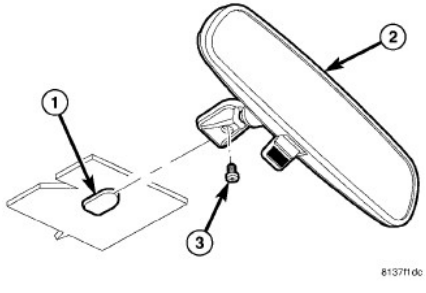
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. If the vehicle is equipped with either the electrochromic (automatic dimming) or the telematic (hands-free phone) mirror option, disconnect and isolate the battery negative cable.
2. If the vehicle is so equipped, disconnect the electrochromic mirror takeout and connector (1) and/or the telematic mirror takeout and connector (2) of the headliner wire harness from the connector receptacle on the back (windshield side) of the mirror housing (3).



3. Remove the set screw (3) that secures the rear view mirror (2) to the support bracket/button (1) on the inside of the windshield glass.
4. Slide the rear view mirror upward far enough to disengage it from the support bracket/button.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

When equipped, the heated mirror system is activated when the rear window defogger (EBL) system is turned on (Refer to 08 - Electrical/8G - Heated/Cooled Systems/Heated Glass - Operation) . When the heated mirror system is activated, an electric heater grid located behind the glass of each outside rear view mirror becomes energized and produces heat to help clear the mirror of ice, snow, or fog.

If the outside mirror heating grids are both inoperative, (Refer to 08 - Electrical/8G - Heated/Cooled Systems/Heated Glass - Diagnosis and Testing) in this group.

The heating grid behind each outside mirror glass cannot be repaired and the mirror assembly must be replaced if the heating grid is found inoperative or damaged (Refer to 23 - Body/Exterior/MIRROR, Outside Rearview - Removal) .

DESCRIPTION

The automatic day/night mirror uses a thin layer of electrochromic material between two pieces of conductive glass to make up the face of the mirror. When the mirror switch is in the On position, two photocell sensors are used by the mirror circuitry to monitor external light levels and adjust the reflectance of the mirror.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The ambient photocell sensor is located on the forward-facing (windshield side) of the rear view mirror housing, and detects the ambient light levels outside of the vehicle. The headlamp photocell sensor is located inside the rear view mirror housing behind the mirror glass and faces rearward, to detect the level of the light being received at the rear window side of the mirror. When the circuitry of the automatic day/night mirror detects that the difference between the two light levels is too great (the light level received at the rear of the mirror is much higher than that at the front of the mirror), it begins to darken the mirror.

The automatic day/night mirror circuitry also monitors the transmission using an input from the backup lamp circuit. The mirror circuitry is programmed to automatically disable its self-dimming feature whenever it senses that the transmission backup lamp circuit is energized.

The automatic day/night mirror is a completely self-contained unit and cannot be repaired. If faulty or damaged, the entire mirror assembly must be replaced.

CHIME WARNING SYSTEM

The chime warning system uses a piezoelectric speaker that is soldered onto the circuit board of the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) to provide audible indications of various vehicle conditions that may require the attention of the vehicle operator or occupants. The instrument cluster utilizes electronic **chime request** messages received from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) and other modules in the vehicle over the Controller Area Network (CAN) data bus along with hard-wired inputs to monitor many sensors and switches throughout the vehicle. In response to those inputs, the circuitry and programming of the cluster allow it to control the audible outputs that are produced.

The IC is capable of producing the following audible outputs:

- **Slow Rate Repetitive Click** - Repeated **click** tones that are issued at a slow rate of about 90 clicks per minute.
- **Fast Rate Repetitive Click** - Repeated **click** tones that are issued at a fast rate of more than about 180 clicks per minute.
- **Single Chime Tone** - A single **chime** tone.
- **Continuous Repetitive Chime Tone** - Repeated **chime** tones that are issued continuously.

Hard wired circuitry connects the IC and the various chime warning system switch and sensor inputs to their modules and to each other through the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses that are routed throughout the vehicle. These circuits may be connected to each other, to the vehicle electrical system, and to the IC through a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, procedures for proper wire and connector repair, further details on wire harness routing and retention, and pin out and location views for the various wire harness connectors, splices, and grounds.

The chime warning system circuits and components cannot be adjusted or repaired. If the IC circuitry, or the speaker is damaged or ineffective, the entire IC unit must be replaced.

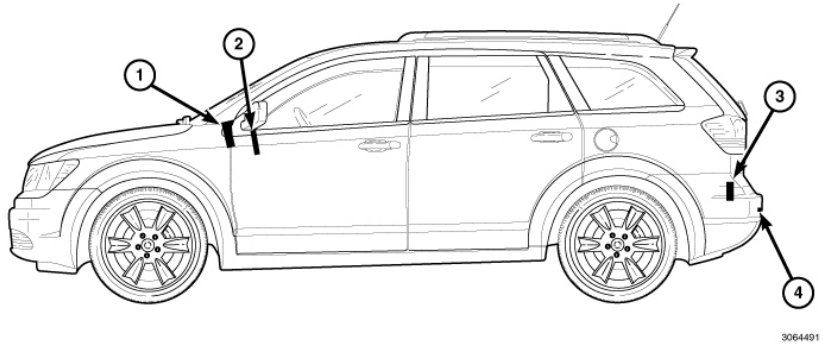
PARK ASSIST SYSTEM



A park assist system is an optional factory-installed electronic parking aid. In some markets only a rear park assist system is offered, while other markets may have both front and rear park assist systems available. During parking and other similar vehicle maneuvers, this system alerts the vehicle operator to obstacles located in the path immediately in front of or behind the vehicle which, due to the surrounding vehicle structures, might be otherwise difficult to perceive. When an object is detected, the system uses a park assist display unit within the instrument cluster, to provide the vehicle operator with visual and audible indications of the presence and proximity of such objects.

The park assist system includes the following major components, which are described in further detail elsewhere in this service information:

- **Electronic Vehicle Information Center (1)** - In vehicles equipped with the optional park assist system, the optional EVIC in the instrument cluster displays textual warnings and error messages, and emits audible warnings related to the current operating status of the park assist system.
- **Park Assist Switch (2)** - The optional park assist system can be manually disabled or enabled using the U-Connect Touch ™ screen module; located in the instrument panel center stack. The operator can select from one of three options under the settings tab to enable or disable the system, the tone alerts, or the visual alerts.
- **Park Assist Module (3)** - Vehicles equipped with the park assist system include a park assist module which is concealed within the molded plastic park assist module housing. There are three mounting tabs integral to the module housing that secure the module to the vehicle body. Two connector receptacles containing terminal pins that connect the module to the vehicle electrical system are integral to the one side of the housing. The module is located at the left rear of the vehicle, behind the rear cargo bin, and beneath the liftgate opening sill plate.
- **Park Assist Sensors (4)** - Vehicles equipped with the rear park assist system have four ultrasonic park assist sensors that are concealed behind the rear bumper fascia. Each sensor is snapped into an individual molded plastic mounting bracket located at horizontal intervals along the back side of the rear bumper fascia.

Hard wired circuitry connects the various park assist system components to each other through the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other and to the vehicle electrical system through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin out and location views for the various wire harness connectors, splices and grounds.

The park assist system components cannot be adjusted or repaired. If any of the park assist system components are damaged in any way, that component must be replaced.

CHIME WARNING SYSTEM

The chime warning system operates on battery voltage received on a non-switched fused B(+) circuit so that the system may operate regardless of the status of the ignition switch. The chime warning system also monitors the ignition switch status so that some chime features are functional only when the status of the ignition switch is On, while others are functional regardless of the ignition switch status.

The chime warning system provides an audible indication to the vehicle operator or occupants under the following conditions:

- **Door Ajar Chime** - The Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) will sound an audible chime when the key is in the ignition and the driver side front door is open. This provides an alert that a door is open or only partially closed. The audible chime will sound when the vehicle begins to move and a visual alert appears within the transmission range indicator of the IC indicating **DOOR**.
- **Enhanced Seat Belt Reminder** - If all the following conditions are met after sixty seconds with the engine On, then the enhanced seat belt reminder feature will be activated.
  - Driver seat belt is unbuckled for ten seconds or more.
  - Vehicle speed is greater than five mph (8 km/h).
  - The transmission gear selector position is not Reverse (**R**) (except in manual transmission vehicles where the reverse position cannot be detected).

  The seat belt indicator will periodically blink, accompanied by a continuous chime for approximately ninety-six seconds or until the driver seat belt is buckled. When the enhanced seat belt feature is not initiated or if the feature is disabled, the seat belt indicator will be turned On continuously until the driver seat belt is buckled. In the same ignition cycle, if the seat belt is again unbuckled for more than ten seconds with the vehicle speed greater than five mph (8 km/h), the enhanced seat belt reminder feature will again be initiated. The enhanced seat belt reminder feature is customer programmable and can be enabled or disabled using a diagnostic scan tool, or by the customer completing a specific sequence of steps as follows:

  1. With the ignition status not Run or Start, buckle the driver seat belt.
  2. Transition the ignition status to the Run or Start and wait for the seat belt reminder check to be completed.
  3. Unbuckle and then re-buckle the driver seat belt causing the indicator to go On and Off three or more times ending with the seat belt buckled.
  4. Return the ignition to any non-Run or non-Start status. The feature will toggle from the current status and a confirmation chime will sound indicating to the customer that the proper sequence to enable or disable the feature has been successfully completed.

- **Exterior Lamps Left On** - An audible chime tone that indicates the exterior lamps were left On.
- **Fasten Seat Belts** - At power up, the IC will conduct a seat belt lamp bulb check. If the driver side seat belt buckle is unbuckled during the bulb check, an accompanying chime will sound within the duration of the bulb check.
- **Key Left In Ignition** - An audible chime tone that indicates the key was left in ignition.
- **Single Warning Chime** - After a bulb check at power-up, if any of the following indicators are still activated, the IC will sound a single chime tone. ABS, Air Bag, Check Engine, Charging System, Engine Temperature, Low Fuel (after 10 seconds for accurate fuel information), and Brake (if speed is greater than 2 mph).

PARK ASSIST SYSTEM

The park assist system is active only when the ignition switch is in the RUN position, the transmission gear selector lever is in the REVERSE position, and the vehicle speed is less than 16 kph (10 mph), and the system voltage between 10 to 16 volts. The park assist system is enabled from the factory as a default but can be manually disabled or enabled using the U-Connect Touch ™ screen module, under the settings tab, by adding or removing a check mark in the OFF selection box. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Integrated Center Stack Screen - Operation) for more information.

The manual disable feature is provided for trailer towing purposes. With a trailer attached to the vehicle the audible and visible park assist alerts would be incessant whenever the gear selector lever was in the REVERSE position due to the proximity of the trailer to the rear of the vehicle. When the system is disabled, a park assist textual message will appear within the Electronic Vehicle Information Center (EVIC) display.

The microprocessor based park assist module is the central component of the park assist system. It supplies voltage to the park assist sensors, receives and analyzes data from the sensors, calculates and communicates the proper display information Instrument Cluster (IC), performs system diagnostics, and communicates with other electronic modules in the vehicle or with a diagnostic scan tool over the Controller Area Network (CAN) data bus. The module operates on battery voltage received through a fuse in the Power Distribution Center (PDC), and is grounded through a take out of the body wire harness.

Four ultrasonic park assist sensors in the rear bumper fascia allow the park assist system to locate and identify the proximity of nearby obstacles. These sensors each generate ultrasonic sound pulses when triggered by the park assist module, then signal the module when an echo of the reflected sound pulses is received. The detection distance range from the rear of the vehicle is about 0.3 meters (11.8 inches) to about 2.0 meters (80 inches) maximum, and the detection height range from the ground is about 0.2 meters (7.8 inches) to about 0.8 meters (31 inches). The detection area extends somewhat around both rear sides (corners) of the vehicle.

The park assist display, located within the EVIC unit, provides the vehicle operator with a visible warning if the vehicle comes to within about 100 centimeters (39 inches) to 200 centimeters (79 inches) of the detected object. The display is visible to the vehicle operator only when looking forward and an object is detected within the detection zone. The system will also emit a series of short, intermittent, audible beeps and automatically lower the volume of the audio system 20 dB below a set tone alert volume, if the vehicles audio system is turned ON. The audible warning changes from intermittent beeps to a continuous tone as the vehicle comes to within 30 centimeters (12 inches) of a detected object.

When the park assist module monitors a problem in any of the park assist system circuits or components, it stores a fault code or Diagnostic Trouble Code (DTC) in its memory circuit. The park assist module then sends an electronic message over the CAN data bus, and one of several **SERVICE PARK ASSIST SYSTEM** textual and graphical message is displayed within the EVIC display, when the message is received by the IC.

The hard wired circuits between components related to the park assist system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the park assist system or the electronic controls or communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient, and accurate means to diagnose the park assist system or the electronic controls and communication related to park assist system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

DESCRIPTION

The Park Assist display is an integral part of the Electronic Vehicle Information Center (EVIC). The park assist icon is only displayed when an object is detected. An electronic message is sent to the Instrument Cluster (IC) from the park assist module over the Controller Area Network (CAN) data bus when an object is within the detection area. The IC then displays the object detection icon with the corresponding alert bar for the distance and location of the object within the EVIC display. (Refer to 00 - Vehicle Data/Vehicle Information/International Vehicle Control and Display Symbols - Description) .

Depending on market and system capabilities, the display icon has as many as 24 different variations with the corresponding alert bars, depending on size, location and distance of the object being detected. The image will display three solid bars followed by a single tone for maximum distance then will flash and reduce the amount of bars as the proximity to the object is reduced followed by a repetitive tone, down to a single bar with a continuos tone.

The EVIC display is only serviced as a complete unit with the IC. It cannot be adjusted or repaired. If ineffective or damaged, the entire display unit must be replaced. (Refer to 08 - Electrical/8M - Message Systems/Message Center/CENTER, Electronic Vehicle Information - Description) .

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

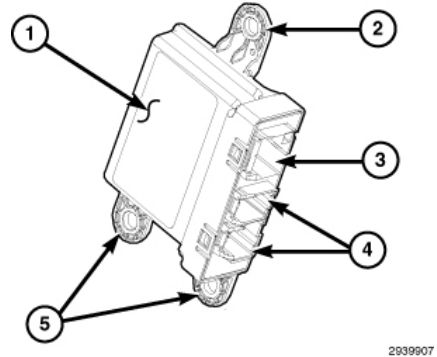
DESCRIPTION

The Park Assist Module (PAM) (1) (also known as the ParkTronic System/PTS module) for this vehicle is located below the lower liftgate opening scuff plate. The module is connected to the vehicle electrical system through dedicated take outs of the body wire harness. Concealed within the molded plastic park assist module housing (1) is a microprocessor and the other electronic circuitry of the module. The module housing is sealed to enclose and protect the internal electronic circuitry. The module software is flash programmable.

There are three mounting tabs (2 and 5) integral to the module housing that secure the module to the vehicle body. The two lower (5) tabs secure the module in place by engaging two slots in the body sheet metal. The upper tab (2) is secured by a push-pin type plastic retainer. Three connector receptacles (3 and 4) containing terminal pins that connect the module to the vehicle electrical system are integral to the one side of the housing. Two of the receptacles are utilized in vehicles equipped with only the rear park assist system, while three receptacles are used on vehicles equipped with both the front and rear park assist systems.

The park assist module cannot be adjusted or repaired and, if damaged or ineffective, it must be replaced with a new unit.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The microprocessor in the Park Assist Module (PAM) contains the logic circuits that control the park assist system. The module uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool using the Controller Area Network (CAN) data bus. This method of communication is also used for park assist system diagnosis and testing through the 16-way data link connector located on the driver side lower edge of the instrument panel.

The module provides voltage to each of the park assist sensors located behind the front and rear bumper fascias and to the front and rear park assist displays. The module then monitors return inputs from each of the sensors and the displays on dedicated hard wired data communication circuits. The sensor inputs allow the module to determine when an obstacle is in the front or rear path of the vehicle and enables the module to calculate the relative location of the obstacle, and whether the distance to that obstacle is increasing or decreasing.

Pre-programmed decision algorithms and calibrations allow the module microprocessor to determine the appropriate park assist system outputs based upon the inputs received from the park assist sensors and electronic messages received from other modules in the vehicle over the CAN data bus. When the programmed conditions are met the module sends electronic messages to the park assist displays over a dedicated serial bus to obtain the proper park assist system visual and audible outputs. The module also broadcasts electronic messages over the CAN data bus to enable the other electronic features of the park assist system.

The PAM microprocessor continuously monitors all of the park assist system electrical circuits and components to determine the system readiness. If the module detects a monitored system fault, it sets a Diagnostic Trouble Code (DTC) and sends the appropriate electronic messages to the instrument cluster over the CAN data bus to control operation of certain park assist system audible warnings and textual messages displayed in the reconfigurable display of the instrument cluster.

The PAM receives battery current on a fused ignition switch output (run-start) circuit through a fuse in the Total Integrated Power Module (TIPM). The module receives ground through a ground circuit and take out of the underbody wire harness. These connections allow the module to be operational whenever the ignition switch is in the START or ON positions.

The hard wired circuits between components related to the park assist module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the PAM or the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the PAM or the electronic controls and communication related to park assist system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

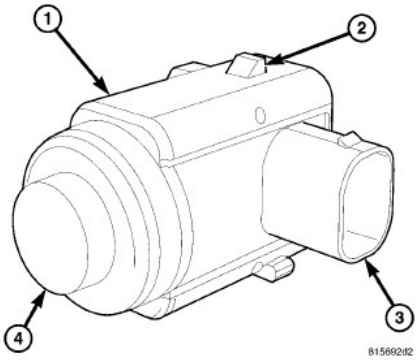
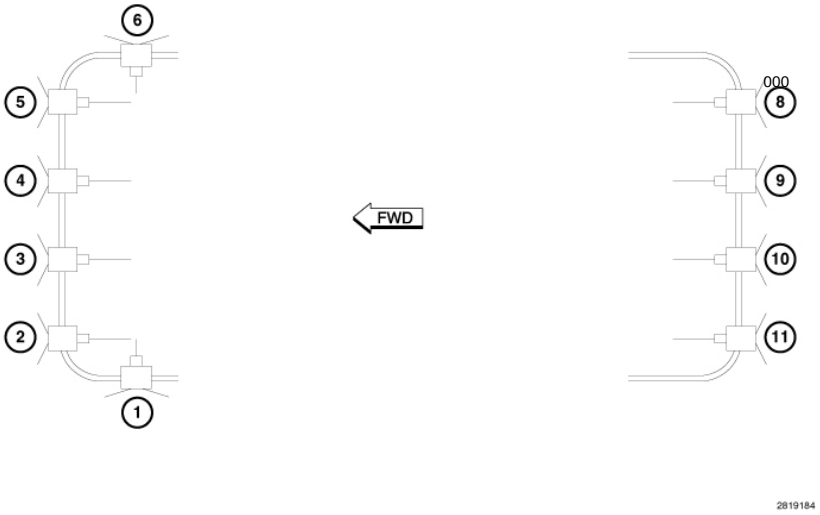
DESCRIPTION

Vehicles equipped with the rear park assist system have four park assist sensors (1) installed on the rear bumper fascia. Vehicles with the front park assist system have six additional sensors installed on the front bumper fascia. Only the membrane (4) of each sensor is visible through a hole in the outer vertical surface of the fascia. The remainder of each sensor including the sensor mounting bracket, the sensor spacer and the sensor wiring connection is concealed behind the fascia. A sensor wire harness behind the fascia connects the sensors to the vehicle electrical system.



Each of the sensors is identical in construction and is interchangeable. The electronic circuitry and a communication chip for each sensor is enclosed and protected within the molded black plastic sensor housing. The housing includes an integral connector receptacle (3) and two integral mounting tabs (2). The sensor membrane extends from the surface of the sensor housing, and is either black or is finished to match the outer surface of the fascia or fascia molding.



The numbering system for the park assist sensors allows for up to twelve sensors on the vehicle, six front and six rear. However, only ten are utilized on this specific vehicle. The sensors are numbered in a clockwise manner starting at the left front bumper. The left front sensor (if equipped with front park assist) is the number 1 sensor. The numbering continues in a clockwise direction around the vehicle, so the left rear sensor is the number 11 sensor.

A resilient O-ring spacer (also known as a decoupling ring) around the circumference of the membrane isolates the membrane from the openings in the fascia or the fascia molding. Each sensor is snapped into its own dedicated molded plastic mounting bracket. Each rear mounting bracket has integral mounting tabs that snap into openings in the horizontal tabs of the molding that extend through slots to the back side of the rear fascia. The front mounting brackets are heat-staked to the back side of the front fascia.

The park assist sensors cannot be adjusted or repaired. If a sensor is ineffective or damaged it must be replaced with a new unit. The sensor spacers and the sensor mounting brackets are each available for individual service replacement.

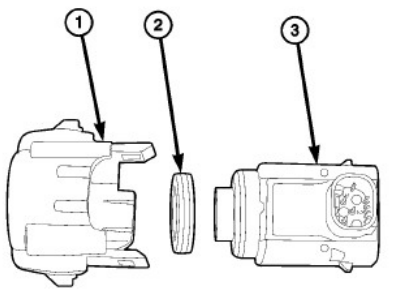
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **The outside sensors are located in the area of the engine exhaust; allow exhaust to cool before accessing the sensors. Failure to follow these instructions may result in personal injury.**

NOTE: The park assist sensors and the sensor spacers (O-rings) are each available for separate service replacement. The following service procedure can be used for reassembling any or all of these components to the rear bumper fascia.

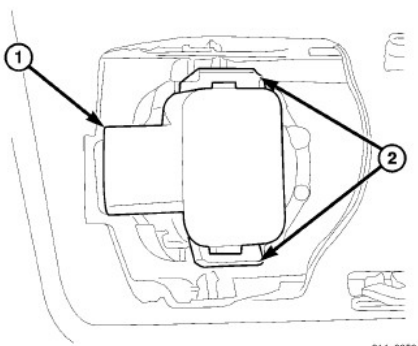
NOTE: Production and all service replacement O-ring spacers are tapered. The wide side (base) of the O-ring should be seated against the sensor housing and the narrow side should be oriented toward the outer surface of the sensor membrane and the rear fascia.



8156ddce

1. If the park assist sensor (3) or the sensor spacer (2) are being replaced, engage the O-ring spacer around the circumference of the sensor membrane protrusion.

NOTE: Be certain that each sensor membrane is properly centered in the openings of the rear fascia and that the O-ring spacers are not pinched. Improper centering or pinched O-rings can be detrimental to proper park assist sensor operation.



814e8852

2. Align and insert the sensor into the sensor bracket on the back of the rear bumper fascia until the bracket latch features (2) are fully engaged over the top and bottom latch tabs of the sensor. Be certain that the sensor membrane is flush with the outer surface of the fascia.
3. From the back of the fascia, reconnect the wire harness connector to the sensor connector receptacle (1).
4. Reconnect the negative cable to the battery.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The park assist sensors are ultrasonic transceivers that are completely controlled by the Park Assist Module (PAM). The sensors transmit and receive ultrasonic signals. The sensors each receive battery current and ground in parallel from the PAM, but are each connected to individual dedicated serial bus communication circuits to the module.

Each sensor membrane is oscillated, then quieted by the PAM in a pulsing fashion. While the sensor membrane oscillates, it emits an ultrasonic signal. This signal will bounce or echo off of objects in the path of the vehicle. While quieted, each membrane receives the echoes of the ultrasonic signals it and the other sensors have transmitted. The sensors then communicate this echo data over the serial bus lines back to the PAM. The microprocessor in the PAM uses the intervals between the ultrasonic transmission and reception data from the sensors to calculate the distance to any obstacles identified by the ultrasonic echoes.

The hard wired circuits between components related to the park assist sensors may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the park assist sensors or the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the park assist sensors or the electronic controls and communication related to park assist sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

DESCRIPTION

The park assist OFF switch is a virtual push button (also known as a soft key) integral to the instrument panel Integrated Center Stack (ICS) display, also known as the Uconnect™ Touch screen module. The park assist system can be manually disabled or enabled using the Uconnect™ Touch screen module controls found under the Settings tab. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Integrated Center Stack Screen - Operation) .

The Uconnect™ Touch screen module cannot be adjusted or repaired and, if the park assist OFF switch is ineffective or damaged, the entire ICS must be replaced with a new unit. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Integrated Center Stack Screen - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The status of the park assist controls is continually monitored by the Integrated Center Stack (ICS) display, also known as the Uconnect™ Touch screen module. The ICS receives battery voltage at all times on a fused battery feed circuit, and a path to ground at all times through the instrument panel wire harness. The inputs to, and outputs from the ICS consist of electronic message communication with the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the Controller Area Network (CAN) data bus.

Each time a park assist control is used, the ICS circuitry sends an electronic **park assist switch status** message input to the BCM over the CAN data bus. The BCM then relays an electronic **park assist switch request** message to the Park Assist Module (PAM) over the CAN data bus. The PAM responds to each **park assist switch request** message by toggling the status of the park assist system from enabled to disabled, or from disabled to enabled, then sends an electronic **park assist system status** message back to the BCM over the CAN data bus as confirmation.

The BCM responds to the system status message received from the ICS by sending a message to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) over the CAN data bus to display a **PARK ASSIST SYSTEM OFF** in the Electronic Vehicle Information Center (EVIC) display whenever the system has been disabled. The message will display each time the status of the ignition switch is ON or START, and remains that way until a bus message is received that the system has been enabled.

The hard wired circuits between components related to the park assist switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the park assist switch or the electronic controls and communication related to park assist system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

DESCRIPTION

The Hands Free Module (HFM) (3) (also known as the Bluetooth™ module) is found in vehicles equipped with the optional Uconnect® Hands-Free System. This module is located beneath the instrument panel and above the steering column. The HFM hardware and circuitry is contained and protected within a molded black plastic housing that has two integral mounts (2) and an integral locating pin (1). The HFM is positioned to a stamped metal steering column mounting bracket by the locating pin, then secured to the bracket by two screws.

The HFM has three integral connector receptacles that are oriented toward the dash panel when it is installed in the vehicle. The two largest receptacles (5 and 6) connect the HFM to the vehicle electrical system through dedicated take outs and connectors of the instrument panel wire harness. The smallest connector (4) accepts a Universal Serial Bus (USB) cable connector that connects the HFM to the Radio Receiver Module (RRM) (also known as the radio or the head unit).

The internal circuitry of the HFM includes a microcontroller, flash memory and a Bluetooth™ module. The module also includes sophisticated Voice Recognition (VR) software. The HFM software is flash programmable.

The HFM cannot be adjusted or repaired and, if damaged or ineffective, the entire HFM must be replaced.

OPERATION

The Hands Free Module (HFM) (also known as the Bluetooth™ module) is used only in vehicles equipped with the optional Uconnect™ Hands-Free Communication System. The HFM contains the microcontroller, logic and memory circuits of the Hands-Free Communication System. The HFM uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool using the Controller Area Network (CAN) data bus. This method of communication is also used for Hands-Free Communication System diagnosis and testing through the 16-way data link connector located on the driver side lower edge of the instrument panel and is used by the HFM to acquire vehicle configuration data.

The HFM brings together several technologies in the vehicle. The HFM uses Bluetooth® technology to provide wireless connectivity between a paired compatible personal cellular telephone or a paired personal wireless audio streaming device and other on board vehicle systems. The HFM also uses sophisticated Voice Recognition (VR) software to recognize and respond appropriately to certain verbal commands, which allows hands-free control of a number of optional vehicle systems and features. In addition to English, the VR software includes Spanish and French language capability. Incoming call voices are broadcast through the front audio system speakers of the vehicle, automatically overriding any other audio signals on the front speakers while the Hands-Free Phone is in use.

The HFM circuitry receives battery current through a fused ignition output (unlock - run - start) circuit and fuse through the Body Control Module (BCM) (also known as the Common Body Controller/CBC). The HFM also has a path to ground at all times received through a ground circuit and take out of the instrument panel wire harness that is secured to the body sheet metal. These connections allow the HFM to operate whenever the status of the ignition switch is Unlock, Run or Start. Other inputs to the HFM include:

- **Cellular Telephone** - Using the Bluetooth® wireless standard, the Bluetooth® transceiver within the HFM can pair and prioritize up to 10 combined personal cellular telephones and Bluetooth® capable portable media devices, each of which is given a spoken identification by the user during the setup process. The phone connectivity enables wireless calling, text messaging and cellular phone contact list synchronization features. The HFM will communicate with a paired device that is anywhere within the vehicle. However, placing metal between the HFM and the device may result in unwanted shielding of the signals.
- **Electronic Vehicle Information Center Switch Pod** - Vehicles equipped with the Uconnect™ Hands-Free feature have two push buttons added to the Electronic Vehicle Information Center (EVIC) switch pod located in the left horizontal spoke of the steering wheel. One push button is labeled **VR** (Voice Recognition) and initiates the Uconnect™ Voice Command feature. The second button is identified by a telephone hand set icon and initiates the Uconnect™ Hands-Free Phone feature. The HFM monitors electronic messages received over the CAN data bus from the Steering Control Module (SCM) indicating the status of each of these two switches.
- **Integrated Center Stack Or Radio Receiver Module Display Screen Virtual Switches** - Vehicles equipped with the Uconnect™ Hands-Free feature have two virtual (soft) push buttons available within the display of the Radio Receiver Module (RRM) or the Integrated Center Stack (ICS), as the vehicle is equipped. Either display is located in the instrument cluster bezel above the instrument panel center stack. One virtual push button is labeled **VR** (Voice Recognition) and activates the Uconnect™ Voice Command feature. The second button is identified by a telephone hand set icon and activates the Uconnect™ Hands-Free Phone feature. The HFM monitors electronic messages received over the CAN data bus from the RRM or the ICS indicating the status of each of these two switches.
- **Streaming Audio** - BlueTooth® Streaming Audio (BTSA) allows audio content from any paired personal Bluetooth® capable portable media device or from an internet radio application on a Bluetooth® capable smart phone to be accessed and listened to through the audio system of the vehicle.
- **Universal Serial Bus** - For music stored on a Universal Serial Bus (USB) flash drive or a Secure Digital (SD) memory card, the HFM receives metadata such as artist names and song titles from the RRM over a dedicated USB connection. This allows the audio content of these connected devices to be searched for and accessed using the Uconnect™ Voice Command feature.
- **Verbal Commands** - Two wired microphones integral to the inside rear view mirror provide verbal commands from the vehicle operator to both the HFM and the RRM, which enables the control of several vehicle systems and features using the Uconnect™ Voice Command feature through the Voice Recognition (VR) software. **Note:** The optional navigation system uses dedicated VR software located within the RRM for that system, not the VR software within the HFM. However, the navigation system shares the inside rear view mirror microphone inputs with those of the HFM.

Outputs of the HFM include:

- **Analog Audio Outputs** - The HFM has both left and right channel analog audio output circuits. The HFM provides Uconnect™ Hands-Free call audio, BlueTooth® Streaming Audio (BTSA) and Hands-Free voice prompt audio to the RRM through these circuits.
- **Digital Electronic Messages** - The VR software within the HFM is programmed to convert Uconnect™ Voice Command verbal inputs into the appropriate electronic request message, which is then transmitted by the HFM over the CAN data bus. When the Electronic Control Unit (ECU) that controls the requested feature receives the electronic request message over the CAN data bus, it will invoke the requested action.
- **Wireless Messages** - The VR software within the HFM is also programmed to convert Uconnect™ Voice Command verbal inputs into the appropriate Bluetooth® wireless request message, which is then transmitted by the Bluetooth® transceiver to the appropriate paired wireless device to invoke the requested action.

The HFM uses On-Board Diagnostics (OBD) to monitor all of the systems and circuits it controls, then sets active and stored Diagnostic Trouble Codes (DTC) for any monitored system faults it detects. The HFM will also send electronic message requests to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) for the display of certain textual warning messages related to some detected system conditions or faults.

The hard wired circuits of the HFM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the HFM or the electronic controls and communication between modules and other devices that provide some features of the Uconnect™ system. The most reliable, efficient and accurate means to diagnose the HFM or the electronic controls and communication related to Uconnect™ system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

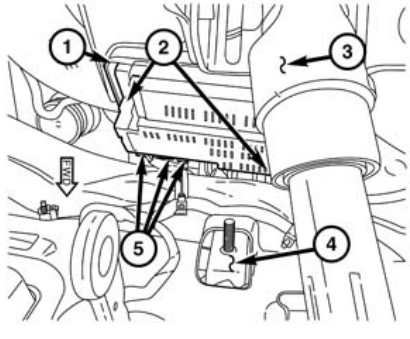
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: The Hands Free Module (HFM) (1) is mounted above the steering column (3) and against the dash panel (4) to the underside of the instrument panel column support bracket.



0811005295

1. Disconnect and isolate the negative cable from the battery.
2. Remove the knee blocker from the instrument panel steering column opening. (Refer to 23 - Body/Instrument Panel/KNEEBLOCKER - Removal) .
3. Remove the brake pedal assembly from the dash panel (4). (Refer to 05 - Brakes/Hydraulic /Mechanical/PEDAL(S) , Brake and/or Accelerator - Removal).

NOTE: One of the HFM mounting screws is concealed between the forward (connector) side of the module and the dash panel.

4. Remove the two screws (2) that secure the Hands Free Module (HFM) (1) to the underside of the instrument panel column support bracket.
5. Lower the HFM far enough to access and disconnect the three wire harness connections (5) from the module connector receptacles.
6. Remove the HFM from above the steering column (3) and under the instrument panel.

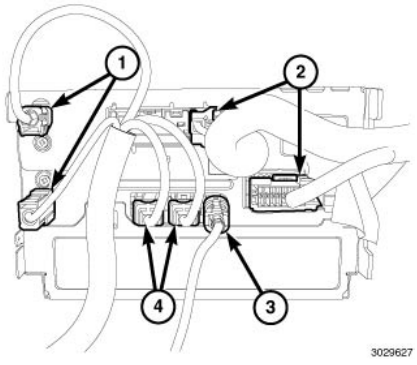
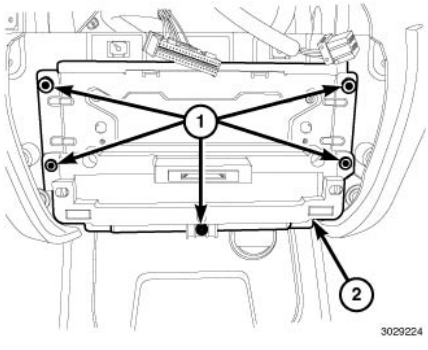
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

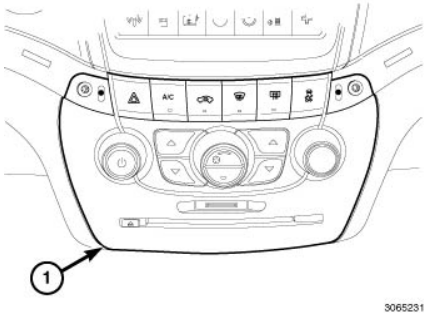
1. Connect the antenna(s) (1), Hands Free Module (HFM) and UCI cables (4), video cable (3) and wiring connectors (2) to the Telematics Gateway Module (TGW).
2. Position the TGW into the mounting location.



3. Install the retainers (1) to the TGW.



4. Install the switch bank assembly. (Refer to 08 - Electrical/8J - Instrument Cluster/POD, Switch Bank - Installation) .
5. Connect the negative battery cable.
6. Restore user data from backup. (Refer to 08 - Electrical/8A - Audio and Video - Standard Procedure) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Telematics Gateway Module (TGW) is responsible for the displayed information on the Integrated Center Stack (ICS) Screen Module over the CAN-AT bus.

The user input from the ICS Screen Module sends the information over the CAN-AT to the TGW, the TGW then sends the command out to the CAN-I bus to the requested module. The requested module then makes the changes requested by the users input and sends a message back to the TGW, the TGW then send the message over the CAN-AT to the ICS to reflect the users input selection has been activated and or changed.

The TGW is responsible for the following.

- Displaying information on the Integrated Center Stack (ICS) Screen Module.
- Passing user input to the correct module on the CAN bus.
- Turning the specific areas (buttons) on the screen usable for user interaction.
- CD/DVD operations
- SD card operations (Mid level only)

If the screen displays **Shipping Mode**, (Refer to 08 - Electrical/8F - Engine Systems/Battery System - Standard Procedure) .

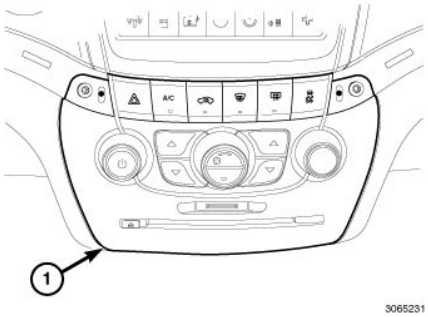
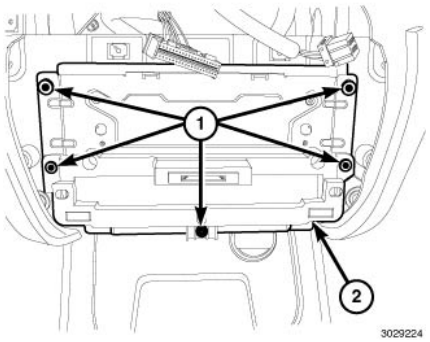
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Perform a complete backup of user data. (Refer to 08 - Electrical/8A - Audio and Video - Standard Procedure) .
2. Disconnect the negative battery cable.
3. Remove the switch-bank and bezel assembly (1). (Refer to 08 - Electrical/8J - Instrument Cluster/POD, Switch Bank - Removal) .

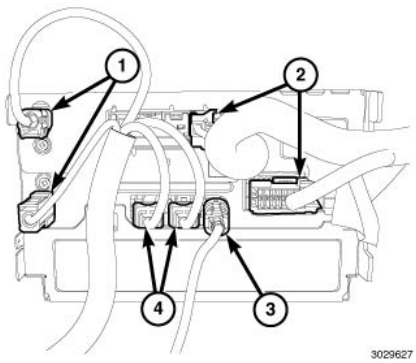


4. Remove the retainers (1) from the Telematics Gateway Module (TGW) (2) and pull out far enough to access the connectors on the back of the TGW.



CAUTION: **Pulling the antenna cable straight out of the radio without pulling on the locking antenna connector could damage the cable or radio.**

5. Disconnect the antenna(s) (1), Hands Free Module (HFM) and UCI cables (4), video cable (3) and wiring connectors (2) from the TGW.
6. Remove the TGW from the vehicle.



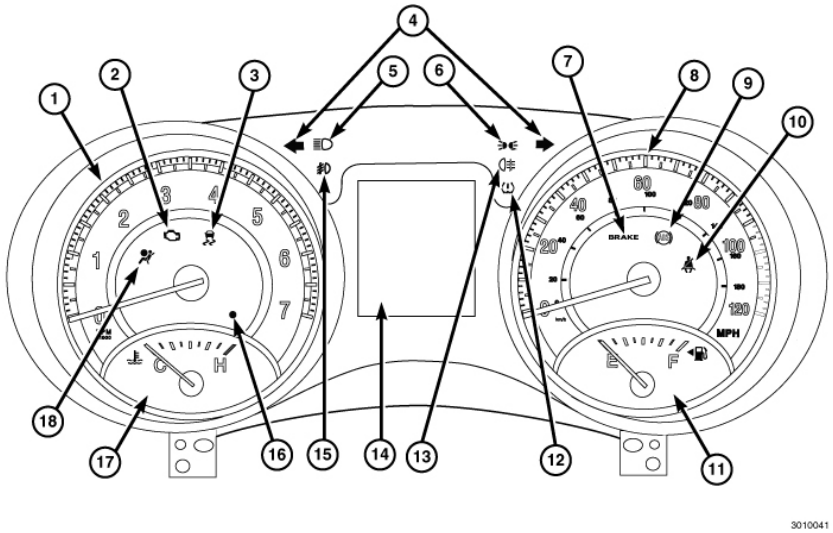
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The Instrument Cluster (IC) assembly has provisions for up to 19 International Control and Display Symbol icon indicators that are all controlled by the IC. Some of the indicators are automatically configured when the IC is connected to the vehicle electrical system for compatibility with certain optional equipment or equipment required for regulatory purposes in certain markets. While each IC may have provisions for indicators to support every available option, the configurable indicators will not function in vehicles that do not have the equipment that an indicator supports.

A dedicated Light Emitting Diode (LED) soldered onto the circuit board illuminates each indicator in the IC, except those within an electronic display unit. Several dimmable LED units illuminate each gauge dial face for visibility when the exterior lighting is turned ON. These LED units are not available for service replacement and, if damaged or ineffective, the entire IC must be replaced.



The instrument cluster includes provisions for the following ISO icon indicators:

- **Airbag Indicator (18)**
- **Antilock Brake System (ABS) Indicator (9)**
- **Brake Indicator (7)**
- **Electronic Stability Control (ESC) Indicator (3)**
- **ESC OFF Indicator (14)** - textual message in the Thin Film Transistor (TFT) display.
- **Front Fog Lamp Indicator (15)**
- **High Beam Indicator (5)**
- **Low Fuel Indicator (14)** - icon in the TFT display.
- **Malfunction Indicator Lamp (MIL) (2)**
- **Position Lamp Indicator (6)**
- **Rear Fog Lamp Indicator (13)** - in markets where rear fog lamps are available only.
- **Seat Belt Indicator (10)**
- **Security Indicator (16)**
- **Tire Pressure Monitor (TPM) Indicator (12)**
- **Turn Signal (Right and Left) Indicators (5)**

Many systems and features found in this vehicle display messages or icons within the TFT (14). The IC includes provisions for the following ISO icon indicators or textual messages within this display:

- **Change Oil Indicator** - icon in the TFT display.
- **Check Gauges Indicator** - textual message in TFT display.
- **Coolant Low Indicator** - icon in the TFT display.
- **Cruise Indicator** - textual message in the TFT display.

- **Electronic Throttle Control (ETC) Indicator** - icon in the TFT display.
- **Gas Cap Indicator** - icon in the TFT display.
- **Low Brake Fluid Level Indicator** - textual message in TFT display.
- **No Bus Indicator** - textual message in TFT display.
- **Odometer** - in TFT display.
- **Park Assist Disabled Indicator** - icon in the TFT display.
- **Power Liftgate Indicator** - an icon in the TFT display.
- **Remote Start Indicator** - textual message in TFT display.
- **Service Park Assist System Indicator** - textual message in TFT display.
- **Transmission Overtemp Indicator** - icon in the TFT display.
- **Turn-Signal-On Reminder Indicator** - textual message in TFT display.
- **Washer Fluid Indicator** - icon in the TFT display.
- **Wait-To-Start Indicator** - icon in the TFT display (diesel engines only).
- **Water-In-Fuel Indicator** - icon in the TFT display (diesel engines only).

For more information on the International Control and Display Symbol icons, (Refer to 00 - Vehicle Data/Vehicle Information/International Vehicle Control and Display Symbols - Description) .

Each indicator in the IC, except those located within an electronic display unit, is illuminated by a dedicated Light Emitting Diode (LED) unit that is soldered onto the IC electronic circuit board. Cluster illumination is accomplished by several dimmable LED units, which illuminate each of the gauge dial faces for visibility when the exterior lighting is turned ON. These LED units are serviced only as a complete unit with the IC and, if damaged or ineffective, the entire IC assembly must be replaced. The cluster lens and the cluster hood and mask unit are the only components of the IC that can be serviced separately.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

Indicators are located in various locations within the Instrument Cluster (IC) and are all connected to the electronic circuit board. All of the indicators are completely controlled by the IC. The various indicators are controlled by different strategies; some receive fused ignition output from the IC circuitry and have a switched ground, while others are grounded through the IC circuitry and have a switched battery feed. However, most are controlled by (CAN) or Local Interface Network (LIN) data bus messages from other electronic modules in the vehicle while others are controlled by a combination of hard wired inputs, electronic messaging and IC programming. If the IC loses CAN data bus communication, the IC circuitry will automatically turn ON the Malfunction Indicator Lamp (MIL) until CAN data bus communication is restored.

In addition, certain indicators in this IC are automatically or self-configured. This feature allows the configurable indicators to be enabled by the IC circuitry for compatibility with certain optional equipment. These indicators are enabled or disabled by an electronic **configuration** message sent to the IC by the Body Control Module (BCM) (also known as the Common Body Controller/CBC). The BCM defaults for the Antilock Brake System (ABS) and the airbag indicators is enabled. These configuration settings must be programmatically disabled in the BCM using a diagnostic scan tool for vehicles that do not have this equipment. The automatically or self-configured indicators remain latent in the IC at all times and will be active only when the IC receives the appropriate CAN or LIN bus message inputs for that optional system or equipment.

The hard-wired indicator inputs may be diagnosed using conventional diagnostic tools and procedures. However, the IC circuitry and electronic CAN or LIN data bus message controlled indicators are diagnosed using the self-diagnostic IC **Self test**. (Refer to 08 - Electrical/8J - Instrument Cluster - Diagnosis and Testing) for more information. For proper testing of the CAN or LIN data bus and the electronic data bus message inputs to the IC that control each indicator requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

Below are brief explanations of the indicators available on this vehicle. More detailed information may be available elsewhere in this service information, located within the section covering the system or component that control or influence the illumination of that indicator. The indicators, the TFT display, the LED units as well as the gauges are only serviceable with the IC as an assembly. The cluster lenses and the hood and mask assembly may be serviced separately from the IC.

ABS INDICATOR

The ABS indicator gives an indication to the vehicle operator when the ABS system, or a circuit or component of the system is ineffective. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the cluster from the CAB over the CAN data bus. The IC will illuminate the ABS indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The ABS indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the status of the ignition switch is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the ABS indicator for the following reasons:

- **ABS Indicator Lamp-On Message** - Each time the IC receives an electronic **ABS indicator lamp-ON** message from the CAB, the ABS indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **Communication Error** - If the IC receives no lamp-ON or lamp-OFF messages from the CAB for five consecutive message cycles, the ABS indicator is illuminated. The indicator remains illuminated until the IC receives a valid message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **ABS Diagnostic Test** - The ABS indicator is blinked ON and OFF by lamp-ON and lamp-OFF messages from the CAB during the performance of the ABS diagnostic tests.

The CAB continually monitors the ABS circuits and sensors to decide whether the system is in good operating condition. The CAB then sends the proper lamp-ON or lamp-OFF message to the IC. If the CAB sends a lamp-ON message after the bulb test, it indicates that the CAB has detected a system malfunction or that the ABS system has become ineffective. The CAB will store a DTC for any malfunction it detects. Each time the ABS indicator fails to light due to an open or short in the IC ABS indicator circuit, the IC sends a message notifying the CAB of the condition, then the IC and the CAB will each store a DTC and the IC will flash the brake indicator ON and OFF as a backup to notify the vehicle operator.

For proper diagnosis of the anti-lock brake system, the CAB, the IC, the CAN data bus or the electronic communication related to ABS indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

AIRBAG INDICATOR

The airbag indicator gives an indication to the vehicle operator when the airbag system, or a circuit or component of the system is ineffective. The airbag indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the Occupant Restraint Controller (ORC) over the CAN data bus. The IC will illuminate the airbag indicator for about six seconds as a bulb test each time the ignition switch status transitions to ON.

The airbag indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the airbag indicator for the following reasons:

- **Airbag Indicator Lamp-On Message** - Each time the IC receives an electronic **airbag indicator lamp-ON** message from the ORC, the airbag indicator will be illuminated. The indicator remains illuminated for about 12 seconds or until the IC receives a lamp-OFF message from the ORC, whichever is longer. This indicator will also be extinguished when the ignition switch status transitions to OFF.
- **Communication Error** - If the IC receives no lamp-ON or lamp-OFF messages from the ORC for 10 consecutive message cycles, the airbag indicator is illuminated. The indicator remains illuminated until the IC receives a single lamp-OFF message from the ORC.

The ORC continually monitors the airbag system circuits and sensors to decide whether the system is in good operating condition. The ORC then sends the proper lamp-ON or lamp-OFF message to the IC. If the ORC sends a lamp-ON message after the bulb test, it indicates that the ORC has detected a system malfunction or that the airbags and seat belt tensioners may not deploy when required, or may deploy when not required. The ORC will store a DTC for any malfunction it detects. Each time the

airbag indicator fails to illuminate due to an open or short in the IC airbag indicator circuit, the IC sends a message notifying the ORC of the condition, then the IC and the ORC will each store a DTC.

For proper diagnosis of the airbag system, the ORC, the IC, the CAN data bus or the electronic communication related to airbag indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

AJAR INDICATORS

The ajar indicators give an indication to the vehicle operator that one or more of the passenger compartment doors or the liftgate may be open or not completely latched. These indicators are controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the Body Control Module (BCM) over the CAN data bus. The BCM monitors hard-wired inputs from the door and liftgate ajar switches.

The ajar indicator function of the TFT electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused B(+) circuit. Therefore, the ajar indications can occur regardless of the ignition switch position. The IC will turn ON an ajar indicator for the following reasons:

- **Ajar Indicator Lamp-On Message** - Each time the IC receives an electronic **door ajar indicator lamp-on** or **liftgate ajar indicator lamp-on** message from the BCM indicating that a door or the liftgate or a combination of these is open or not completely latched, the appropriate ajar textual message and icons will be illuminated. If the IC detects a vehicle speed input greater than zero (kilometers or miles-per-hour) while the ignition switch status is ON or START, the ajar indication will be accompanied by a single chime tone. When the ignition switch status is anything except ON or START, any and all ajar indications will time out after about five minutes.

The ajar switches on the door and liftgate latch mechanisms provide hard-wired ground inputs to the BCM circuitry through the ajar switch sense circuits whenever a door or the liftgate is open or not completely latched. The BCM continually monitors the door and liftgate ajar switches to determine the status of the doors and liftgate, then sends the proper electronic **ajar indicator lamp-on** or **lamp-off** message to the IC.

The hard wired ajar switch inputs to the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. For proper diagnosis of the BCM, the IC, the CAN data bus or the electronic communication related to ajar indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

BRAKE/PARK BRAKE INDICATOR

The brake indicator gives an indication to the vehicle operator when the parking brake is applied, when there are certain brake hydraulic system malfunctions as indicated by a low brake hydraulic fluid level condition or when the brake fluid level switch is disconnected. The brake indicator can also give an indication when certain faults are detected in the Antilock Brake System (ABS). This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the CAB or the Body Control Module (BCM) over the CAN data bus. The BCM monitors the hard wired input from the park brake switch. The IC will illuminate the brake indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The brake indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the brake indicator for the following reasons:

- **Brake Indicator Lamp-On Message** - Each time the IC receives an electronic **brake indicator lamp-ON** message from the CAB, the brake indicator will be illuminated. The CAB may also send lamp-ON messages as feedback during ABS diagnostic procedures. The indicator remains illuminated until the IC receives a lamp-OFF message from the CAB or until the ignition switch status transitions to OFF, whichever occurs first.
- **Low Brake Fluid Textual Warning Message** - When the CAB detects a low brake fluid level input from the brake fluid level switch, it will send an electronic **textual warning request** message requesting the IC display a textual warning message. Each time the IC receives this message from the CAB, a **LOW BRAKE FLUID LEVEL** textual message will appear within the IC electronic display to accompany brake indicator illumination. This message indicates that the CAB has detected a low brake fluid level condition in the brake master cylinder or that there is a problem in the brake fluid level switch or circuits.
- **Park Brake Switch Input** - Each time the IC receives an electronic **brake indicator lamp-FLASH** message from the BCM, the brake indicator will be flashed ON and OFF. While the ignition switch status is ON, the BCM monitors the park brake switch through the park brake switch sense circuit (park brake switch closed = park brake applied or not fully released). The indicator continues to flash until the park brake switch sense input to the BCM is an open circuit (park brake switch open = park brake fully released), or until the ignition switch status transitions to OFF, whichever occurs first.
- **Antilock Brake System (ABS) Indicator Backup** - If the IC detects a fault in the ABS indicator circuit it will send a message indicating the fault to the CAB, then flash the brake indicator ON and OFF. The IC will continue to flash the brake indicator until the ABS indicator circuit fault is resolved, or until the ignition switch status transitions to OFF, whichever occurs first.

The park brake switch on the park brake lever mechanism provides a hard-wired ground input to the BCM circuitry through the park brake switch sense circuit whenever the park brake is applied or not fully released. The CAB continually monitors the ABS system circuits and sensors, including the brake fluid level switch on the brake master cylinder reservoir, to decide whether the system is in good operating condition. The CAB then sends the proper lamp-ON, lamp-OFF or lamp-FLASH message to the IC. If the CAB sends a lamp-ON message after the bulb test, it indicates that the CAB has detected a brake hydraulic system malfunction or that the ABS system has become ineffective. The CAB will store a DTC for any malfunction it detects.

The hard wired park brake switch input to the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. For proper diagnosis of the brake fluid level switch, the ABS, the BCM, the CAB, the IC, the CAN data bus or the electronic communication related to brake indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CHANGE OIL INDICATOR

The change oil indicator gives an indication to the vehicle operator when a duty-cycle algorithm contained within the software of the PCM determines that a recommended oil change interval has been attained. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The change oil indicator function of the IC electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the change oil indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the change oil indicator for the following reasons:

- **Change Oil Indicator Lamp-On Message** - Each time the ignition switch status transitions to ON and the IC receives an electronic **change oil indicator lamp-**

ON message from the PCM indicating that a duty-cycle based recommended oil change interval has been attained, the change oil indicator will be illuminated for about ten seconds, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first.

- **Change Oil Indicator Reset Procedure** - Once an engine oil change has been completed, the PCM duty cycle counters can be reset using the following procedure. Set the ignition switch status to ON, but DO NOT start the engine. Slowly depress and release the accelerator pedal fully three times within ten seconds. The IC will display a textual **OIL CHANGE RESET** message. Set the ignition switch status to OFF. If the change oil indicator illuminates the next time the engine is started, repeat this procedure.

The PCM continually monitors numerous sensor inputs to determine the duty-cycles to which the engine is being subjected. A pre-programmed algorithm within the PCM then determines when to send the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the change oil indicator, the PCM, the IC, the CAN data bus or the electronic communication related to change oil indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CHARGING INDICATOR

The charging indicator gives an indication to the vehicle operator when the electrical system voltage is too low or too high. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus. The IC will illuminate the charge indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The charging indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the charging indicator for the following reasons:

- **Voltage Low Message** - Each time the IC receives an electronic **system voltage** message from the PCM indicating the voltage is low (less than about 11.5 volts is a charge fail condition), the charging indicator will be illuminated. The indicator remains illuminated until the IC receives a message from the PCM indicating the voltage is normal (greater than about 12.0 volts, but less than 16.0 volts), or until the ignition switch status transitions to OFF, whichever occurs first.
- **Voltage High Message** - Each time the IC receives an electronic **system voltage** message from the PCM indicating the voltage is high (greater than about 16.0 volts), the charging indicator will be illuminated. The indicator remains illuminated until the IC receives a message from the PCM indicating the voltage is normal (less than about 15.5 volts, but greater than 11.5 volts), or until the ignition switch status transitions to OFF, whichever occurs first.

The PCM continually monitors the electrical system voltage to control the generator output. The PCM then sends the proper messages to the IC. If the IC turns ON the charging indicator due to a charge fail or voltage high condition, it may indicate that the charging system requires service.

For proper diagnosis of the charging system, the PCM, the IC, the CAN data bus or the electronic communication related to charging indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CHECK GAUGES INDICATOR

The check gauges indicator gives an indication to the vehicle operator when the engine coolant temperature gauge indicates the coolant temperature is high or critical. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The check gauges indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the check gauges indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the check gauges indicator for the following reasons:

- **Engine Temperature High or Critical Message** - Each time the IC receives an electronic **engine coolant temperature** message from the PCM indicating the temperature is high or critical the engine coolant temperature gauge needle is moved to the appropriate position at the high end of the gauge scale, the check gauges textual warning is displayed, and a single chime tone is sounded. The check gauges textual warning remains illuminated until the IC receives a message from the PCM indicating that the temperature is below the high end of normal, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the check gauges textual warning is cycled OFF and then ON again by the appropriate temperature messages from the PCM.

The PCM continually monitors the engine coolant temperature sensor to determine the engine operating temperature. The PCM then sends the proper messages to the IC. If the IC turns on the check gauges indicator due to a high or critical engine temperature gauge reading, it may indicate that the engine or the engine cooling system requires service.

For proper diagnosis of the engine coolant temperature sensor, the PCM, the IC, the CAN data bus or the electronic communication related to check gauges indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

CRUISE INDICATOR

The cruise indicator gives the vehicle operator an indication when the speed control system is ON, regardless of whether the speed control is engaged. This indicator is controlled by the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus.

The cruise indicator LED is completely controlled by the IC logic circuit, and that logic only allows this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED is always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the cruise indicator for the following reasons:

- **Cruise Indicator Lamp-On Message** - Each time the IC receives an electronic **cruise indicator lamp-on** message from the PCM indicating the speed control system is ON, the cruise indicator is illuminated. The indicator remains illuminated until the IC receives a lamp-off message from the PCM, or until the ignition switch status transitions to OFF, whichever occurs first.

The PCM continually monitors the speed control switches to determine the appropriate outputs to control the vehicle speed. The PCM then sends the proper lamp-on or lamp-off message to the IC.

For proper diagnosis of the speed control switches, the PCM, the IC, the CAN data bus or the electronic communication related to cruise indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

ELECTRONIC THROTTLE CONTROL INDICATOR

The Electronic Throttle Control (ETC) indicator gives an indication to the vehicle operator when the ETC system, or a circuit or component of the system is ineffective. The ETC indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus. The IC will illuminate the ETC indicator for about fifteen seconds as a bulb test each time the ignition switch status transitions to ON.

The ETC indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the ETC indicator for the following reasons:

- **ETC Indicator Lamp-On Message** - Each time the IC receives an electronic **ETC indicator lamp-ON** message from the PCM, the ETC indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the PCM message. The indicator remains illuminated solid or continues to flash for about 12 seconds or until the IC receives a lamp-OFF message from the PCM, whichever is longer. If the indicator is illuminated solid with the engine running the vehicle will usually remain drivable. If the indicator is flashing with the engine running the vehicle may require towing. A flashing indicator means the ETC system requires immediate service. The indicator will be extinguished when the ignition switch status transitions to OFF.

The PCM continually monitors the ETC system circuits and sensors to decide whether the system is in good operating condition. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the PCM sends a lamp-ON message after the bulb test, it indicates that the PCM has detected an ETC system malfunction or that the ETC system is ineffective. The PCM will store a DTC for any malfunction it detects. Each time the ETC indicator fails to illuminate due to an open or short in the IC ETC indicator circuit, the IC sends a message notifying the PCM of the condition, then the IC and the PCM will each store a DTC.

For proper diagnosis of the ETC system, the PCM, the IC, the CAN data bus or the electronic communication related to ETC indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

ENGINE TEMPERATURE INDICATOR

The engine temperature indicator gives an indication to the vehicle operator when the engine temperature gauge reading reflects a condition requiring immediate attention. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received from the PCM over the CAN data bus. The IC will illuminate the engine temperature indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The engine temperature indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The engine temperature indicator will also be turned ON for the following reasons:

- **Engine Temperature High Message** - Each time the IC receives a message from the PCM indicating the engine coolant temperature is high, the engine temperature indicator will be illuminated and a single chime tone is sounded. The indicator remains illuminated until a message from the PCM indicating that the engine coolant temperature is below the high end of normal is received, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the engine temperature indicator is cycled off and then on again by the appropriate engine temperature messages from the PCM.

The PCM continually monitors the engine coolant temperature sensor to determine the engine operating temperature. The PCM then sends the proper engine coolant temperature messages to the IC. If the IC turns on the engine temperature indicator due to a high engine temperature gauge reading, it may indicate that the engine or the engine cooling system requires service.

ESC INDICATOR

The Electronic Stability Control (ESC) indicator gives an indication to the vehicle operator when the ESC has been activated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the CAB and the Final Drive Control Module (FDCM) over the CAN data bus. The IC will illuminate the ESC/BAS indicator for about four seconds as a bulb test each time the ignition switch status transitions to ON.

The ESC indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the ESC/BAS indicator for the following reasons:

- **ESC Indicator Lamp-On Message** - Each time the IC receives an electronic **ESC/ indicator lamp-ON** message from the CAB indicating that the ESC system has been activated, the ESC indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **ESC Off Textual Message** - Each time the IC receives an electronic **ESC OFF indicator lamp-ON** message from the CAB indicating that the ESC system has been manually disabled, an **ESC OFF** textual message will appear within the IC electronic display unit. The **ESC OFF** textual message remains displayed until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.
- **ESC Textual Warning Message** - When the CAB or FDCM detects certain monitored fault conditions, it will send electronic messages requesting the IC display a textual warning message. Each time the IC receives an electronic **ESC textual warning request** message from the CAB or FDCM, a **WARNING! LIMIT SPEED** textual message will appear within the IC electronic display unit to accompany an ESC indicator that is illuminated solid. This message indicates that the CAB or FDCM has detected a problem in one of the ESC system circuits or components.

The CAB and FDCM continually monitor the ESC circuits and sensors to decide whether the system is in good operating condition. The CAB or FDCM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the ESC/BAS system, the CAB, the FDCM, the IC, the CAN data bus or the electronic communication related to the ESC/BAS indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

FRONT FOG LAMP INDICATOR

The front fog lamp indicator gives an indication to the vehicle operator whenever the front fog lamps are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the BCM over the CAN data bus.

The front fog lamp indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path

to ground by the IC transistor. The IC will turn ON the front fog lamp indicator for the following reasons:

- **Front Fog Indicator Lamp-On Message** - Each time the IC receives an electronic **front fog indicator lamp-ON** message from the BCM indicating the front fog lamps are turned ON, the front fog lamp indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors a hard wired input from the exterior lighting switch to determine the appropriate outputs to the front fog lamps. The BCM activates or deactivates the front fog lamps then sends the proper lamp-ON or lamp-OFF message to the IC to control the front fog lamp indicator.

For proper diagnosis of the front fog lamp system, the BCM, the IC, the CAN data bus or the electronic communication related to front fog lamp indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

GAS CAP INDICATOR

The gas cap indicator gives an indication to the vehicle operator when there is a gross leak detected in the on-board fuel vapor recovery system. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The gas cap indicator function of the IC electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the gas cap indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the gas cap indicator for the following reasons:

- **Gas Cap Indicator Lamp-On Message** - Each time the IC receives an electronic **gas cap indicator lamp-ON** message from the PCM indicating there is a gross leak in the vapor recovery system, the gas cap indicator will be displayed. The indicator remains displayed until the IC receives a lamp-OFF message from the PCM, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first.

NOTE: If the On-Board Diagnostic (OBD) system in the vehicle determines that the fuel filler cap is loose, improperly installed or damaged, a gas cap ICON will be displayed in the electronic display unit. In this instance, verify that the gas cap is properly installed and tightened before proceeding with any further diagnosis.

The PCM continually monitors the on board vapor recovery system to determine whether there are air leaks in the system. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the gas cap indicator due to a monitored gross leak in the vapor recovery system, it may indicate that the gas cap has been removed or is improperly installed.

For proper diagnosis of the on board vapor recovery system, the PCM, the IC, the CAN data bus or the electronic communication related to gas cap indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

HIGH BEAM INDICATOR

The high beam indicator gives an indication to the vehicle operator whenever the headlamp high beams are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received from the BCM over the CAN data bus.

The high beam indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the high beam indicator for the following reasons:

- **High Beam Indicator Lamp-On Message** - Each time the IC receives an electronic **high beam indicator lamp-ON** message from the BCM or the Automatic High Beam Module (AHBM) (also known as SmartBeam® on vehicles so equipped) the high beam indicator will be illuminated. The high beam indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors electronic messages from the Steering Angle Sensor (SAS) based upon the status of the beam select switch and the AHBM to determine the proper headlamp beam control. The BCM activates or deactivates the headlamp high beams then sends the proper lamp-ON or lamp-OFF message back to the IC.

For proper diagnosis of the SAS, the AHBM, the BCM, the IC, the CAN data bus or the electronic communication related to high beam indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW COOLANT INDICATOR

The low coolant indicator gives an indication to the vehicle operator when the diesel engine coolant level is low. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the PCM.

The low coolant indicator function of the IC electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the low coolant indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the low coolant indicator for the following reasons:

- **Low Coolant Indicator Lamp-On Message** - Each time the IC receives an electronic **low coolant indicator lamp-ON** message from the PCM indicating the engine coolant level is low, the low coolant textual warning and icon are illuminated and a single chime tone is sounded. The low coolant textual warning and icon remain illuminated until the IC receives a lamp-OFF message from the PCM, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the textual warning and icon are cycled OFF and then ON again by the appropriate messages from the PCM.

The PCM continually monitors the engine coolant level switch on the coolant bottle to determine the level of the engine coolant. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the coolant low indicator and icon due to a low coolant level, it may indicate that the engine or the engine cooling system requires service.

For proper diagnosis of the engine coolant level switch, the PCM, the IC, the CAN data bus or the electronic communication related to low coolant indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW FUEL INDICATOR

The low fuel indicator gives an indication to the vehicle operator when the level of fuel in the fuel tank becomes low. This indicator is controlled by a transistor on the IC circuit board based upon programming and a hard wired input received by the IC from the fuel level sending unit on the fuel pump module in the fuel tank. The IC will illuminate the low fuel indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The low fuel indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the low fuel indicator for the following reasons:

- **Less Than 11 Percent Tank Full Input** - The BCM provides a constant current source to the fuel level sending unit, and monitors a return input on a fuel level sense circuit. The resistance through the fuel level sending unit increases as the fuel level falls, and decreases as the fuel level rises causing changes in the sense input voltage. Each time the fuel level sense input to the BCM indicates the fuel tank is about 11 percent full or less for 10 consecutive seconds and the vehicle speed is zero, or for 60 consecutive seconds and the vehicle speed is greater than zero, the BCM sends an electronic message to the IC. Then the IC moves the gauge needle to the appropriate position on the gauge scale; the low fuel indicator is illuminated and a single chime tone is sounded. The low fuel indicator remains illuminated until the fuel level sense input indicates that the fuel tank is greater than about 14 percent full for 10 consecutive seconds and the vehicle speed is zero, or for 60 consecutive seconds and the vehicle speed is greater than zero, or until the ignition switch transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the low fuel indicator is cycled OFF and then ON again by the appropriate inputs from the fuel level sending unit.
- **Less Than Empty Stop Input** - Each time the IC receives a fuel level message from the BCM that indicates the fuel level in the fuel tank is less than the **E** (or Empty) gauge needle stop position for five consecutive seconds, the gauge needle is moved to the low end of the gauge scale and the low fuel indicator is illuminated immediately. This input would indicate that the fuel level sense input to the BCM is a short circuit.
- **More Than Full Stop Input** - Each time the IC receives a fuel level message from the BCM that indicates the fuel level in the fuel tank is more than the **F** (or Full) gauge needle stop position for five consecutive seconds, the gauge needle is moved to the low end of the gauge scale and the low fuel indicator is illuminated immediately. This input would indicate that the fuel level sense input to the BCM is an open circuit.

The BCM continually monitors the fuel tank sending unit to determine the level of fuel in the fuel tank. The BCM then sends the proper electronic **fuel level** message to IC and other electronic modules in the vehicle over the CAN data bus. The BCM will store a DTC for any fault detected in the fuel level sense circuit.

For proper diagnosis of the fuel tank sending unit, the BCM, the IC, and the CAN data bus or the electronic communication related to low fuel indicator operation or fuel level data processing, a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW OIL PRESSURE INDICATOR

The low oil pressure indicator gives an indication to the vehicle operator when the engine oil pressure reading reflects a condition requiring immediate attention. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus.

The low oil pressure indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the low oil pressure indicator for the following reasons:

- **Engine Oil Pressure Low Message** - Each time the IC receives an electronic **engine oil pressure** message from the PCM indicating the pressure is about 6.9 kPa (1 psi) or lower, the low oil pressure indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the PCM message. The indicator remains illuminated solid or flashing until the IC receives a message from the PCM indicating that the pressure is above about 6.9 kPa (1 psi), or until the ignition switch status transitions to OFF, whichever occurs first. The IC will only turn the indicator ON in response to low engine oil pressure if the engine speed is greater than zero.

The PCM continually monitors the engine oil pressure sensor to determine the engine oil pressure. The PCM then sends the proper messages to the IC. If the IC turns ON the indicator after the bulb test, it may indicate that the engine or the engine oiling system requires service.

For proper diagnosis of the engine oil pressure sensor, the PCM, the IC, the CAN data bus or the electronic communication related to low oil pressure indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

LOW TIRE PRESSURE INDICATOR

The Tire Pressure Monitor (TPM) indicator gives an indication to the vehicle operator of the status of the TPM system. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the Tire Pressure Module (TPM) (also known as the CORAX module) over the CAN data bus. The IC will illuminate the TPM indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The TPM indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the TPM indicator for the following reasons:

- **TPM Indicator Lamp-On Message** - Each time the IC receives an electronic **TPM indicator lamp-ON** message from the TPM, the TPM indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the TPM message. The indicator remains illuminated until the IC receives a lamp-OFF message from the TPM, or until the ignition switch status transitions to OFF position, whichever occurs first.
- **TPM Textual Warning Message** - When the TPM detects certain monitored fault conditions, it will send electronic messages requesting the IC display a textual warning message. Each time the IC receives an electronic **textual warning request** message from the TPM, a **SERVICE TIRE PRESS. SYSTEM** textual message will appear within the electronic display unit to accompany a flashing TPM indicator or to replace the TPM **TIRE LOW PRESSURE** textual message. This message indicates that the TPM has detected a problem in one of the TPM system components.
- **TPM Low Pressure Message** - On vehicles equipped with the optional premium version of the TPM system, each time the IC receives an electronic **low pressure** message from the TPM, a **LEFT FRONT**, **RIGHT FRONT**, **LEFT REAR** or **RIGHT REAR LOW PRESSURE** textual message will appear within the IC electronic display unit to accompany a solid TPM indicator. If the vehicle is equipped with a full-sized matching spare tire and wheel assembly, an electronic **spare low pressure** message from the TPM to the IC will cause a **SPARE LOW PRESSURE** textual message to appear in the electronic display unit, but the TPM indicator

will not illuminate. This message indicates that the TPM has received a low tire pressure input from the tire pressure sensor in the identified location on the vehicle. The premium TPM system is not offered in markets where rear fog lamps are an available option.

- **Communication Error** - If the IC receives no TPM lamp-ON or lamp-OFF messages from the TPM for six consecutive seconds, the TPM indicator is illuminated by the IC. The indicator remains controlled and illuminated by the IC until a valid lamp-ON or lamp-OFF message is received from the TPM.

The TPM performs a self-test each time the ignition switch status transitions to ON to decide whether the TPM system is in good operating condition and whether the tire inflation pressures are too high or too low. The TPM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the TPM indicator after the bulb test, it indicates that the inflation pressure of a tire is too low or that a malfunction has occurred and the TPM system is ineffective.

For proper diagnosis of the TPM system, the TPM, the IC, the CAN data bus or the electronic communication related to TPM indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

MALFUNCTION INDICATOR LAMP

The Malfunction Indicator Lamp (MIL) gives an indication to the vehicle operator when the PCM has recorded a DTC for an On-Board Diagnostics II (OBDII) emissions-related circuit or component malfunction. The MIL is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the PCM over the CAN data bus. The IC will illuminate the MIL indicator for about fifteen seconds as a bulb test each time the ignition switch status transitions to ON.

The MIL LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the MIL for the following reasons:

- **MIL Lamp-On Message** - Each time the IC receives an electronic **MIL lamp-ON** message from the PCM, the indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the PCM message. For some DTCs, if a problem does not recur, the PCM will send a lamp-OFF message automatically. Other DTCs may require that a fault be repaired and the PCM be reset before a lamp-OFF message will be sent. For more information on the PCM, and the DTC set and reset parameters, (Refer to 25 - Emissions Control - Operation) .
- **Communication Error** - If the IC receives no lamp-ON or lamp-OFF messages from the PCM for 10 consecutive message cycles, the MIL is illuminated by the IC to indicate a loss of bus communication. The indicator remains controlled and illuminated by the IC until a valid message is received from the PCM.

The PCM continually monitors the fuel and emissions system circuits and sensors to decide whether the system is in good operating condition. The PCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC turns ON the MIL after the bulb test, it may indicate that a malfunction has occurred and that the fuel and emissions systems require service.

For proper diagnosis of the fuel and emissions systems, the PCM, the IC, the CAN data bus or the electronic communication related to MIL operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

NO BUS INDICATOR

The no bus indicator gives an indication to the vehicle operator when the IC detects a loss of electronic communication over the CAN data bus. This indicator is controlled by the IC logic circuit based upon programming and electronic messages not being received over the CAN data bus from the BCM.

The no bus indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the no bus indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the no bus indicator for the following reasons:

- **No Electronic Communication Messages** - Each time the ignition switch is turned to the ON position and the IC does not receive electronic communication messages over the CAN data bus, the no bus indicator is illuminated. The indicator remains illuminated until CAN bus communication is restored or until the ignition switch status transitions to OFF, whichever occurs first.

The IC continually monitors the CAN data bus to determine the status of many sensors and systems throughout the vehicle. If the IC detects the loss of CAN bus communication it illuminates the no bus indicator to alert the vehicle operator that it cannot provide accurate displays and outputs.

For proper diagnosis of the IC, the CAN data bus or the electronic communication related to no bus indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

POSITION LAMP INDICATOR

The position lamp indicator gives an indication to the vehicle operator whenever the position lamps are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the BCM over the CAN data bus.

The position lamp indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the position lamp indicator for the following reasons:

- **Position Lamp Indicator Lamp-On Message** - Each time the IC receives an electronic **position lamp indicator lamp-ON** message from the BCM indicating the position lamps are turned ON, the position lamp indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors a hard wired input from the exterior lighting switch to determine the appropriate outputs to the park lamps. The BCM activates or deactivates the park lamps then sends the proper lamp-ON or lamp-OFF message to the IC to control the position lamp indicator.

For proper diagnosis of the position lamp system, the BCM, the IC, the CAN data bus or the electronic communication related to position lamp indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

POWER LIFTGATE INDICATOR

The power liftgate indicator gives an indication to the vehicle operator of the power liftgate system status or when the system has been automatically disabled. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the Power LiftGate Module (PLGM).

The power liftgate indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the power liftgate indications can be displayed regardless of the ignition switch status. The IC will turn ON the power liftgate indicator for the following reasons:

- **Unlock To Operate Message** - Each time the IC receives an electronic **unlock to operate** message from the PLGM, the **UNLOCK TO OPERATE** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Put In Park To Operate Message** - Each time the IC receives an electronic **put in PARK to operate** message from the PLGM, the **PUT IN PARK TO OPERATE** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Function Disabled Message** - Each time the IC receives an electronic **function disabled** message from the PLGM, the **FUNCTION DISABLED** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Obstacle Detected Message** - Each time the IC receives an electronic **obstacle detected** message from the PLGM, the **OBSTACLE DETECTED** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.
- **Manually Close To Operate Message** - Each time the IC receives an electronic **manually close to operate** message from the PLGM, the **MANUAL CLOSE TO OPERATE** textual message is displayed. The message is displayed for about three seconds or until the IC arbitrator logic determines that another display request has priority, whichever occurs first.

The PLGM continually monitors the power liftgate circuits and sensors to determine the proper outputs to the power liftgate components. The PLGM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the power liftgate, the PLGM, the IC, the CAN data bus or the electronic communication related to power liftgate indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

REAR FOG LAMP INDICATOR

The rear fog lamp indicator gives an indication to the vehicle operator whenever the rear fog lamps are illuminated. This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received by the IC from the BCM over the CAN data bus.

The rear fog lamp indicator LED is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the rear fog lamp indicator for the following reasons:

- **Rear Fog Indicator Lamp-On Message** - Each time the IC receives an electronic **rear fog indicator lamp-ON** message from the BCM indicating that the rear fog lamps are turned ON, the rear fog lamp indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the BCM, or until the exterior lamp load shedding (battery saver) timed interval expires, whichever occurs first.

The BCM continually monitors a hard wired input from the exterior lighting switch to determine the appropriate outputs to the rear fog lamps. The BCM activates or deactivates the rear fog lamps then sends the proper lamp-ON or lamp-OFF message to the IC to control the rear fog lamp indicator.

For proper diagnosis of the rear fog lamp system, the BCM, the IC, the CAN data bus or the electronic communication related to rear fog lamp indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

REMOTE START INDICATOR

The remote start indicator gives an indication to the vehicle operator of the remote start system status. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the BCM and the Radio Frequency Hub (RF Hub).

The remote start indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, the remote start indications can be illuminated regardless of the ignition switch status. The IC will turn ON the remote start indicator for the following reasons:

- **Remote Start Active Messages** - Each time the IC receives an electronic**remote start active** message from the BCM, the **REMOTE START ACTIVE - PUSH START BUTTON** textual message is displayed. The message is displayed while the current remote start event remains active (about 15 minutes), until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to ON, whichever occurs first.
- **Remote Start Abort Messages** - Each time the IC receives a combination of electronic **remote start abort** and **door ajar**, **hood ajar**, **liftgate ajar** or **low fuel** messages from the BCM the **REMOTE START ABORTED** and appropriate **DOOR AJAR**, **HOOD AJAR**, **LIFTGATE AJAR** or **FUEL LOW**textual messages are displayed. The messages are displayed while the current remote start event remains active (about 15 minutes), until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to ON, whichever occurs first.
- **Remote Start Disabled Messages** - Each time the IC receives an electronic **remote start disabled** message from the BCM the **REMOTE START DISABLED - START VEHICLE TO RESET** textual message is displayed. The message is displayed while the current remote start event remains active (about 15 minutes), until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to START, whichever occurs first.

The BCM continually monitors the remote start system inputs and the RF Hub to determine the proper outputs to the remote start components. The BCM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the remote start system, the RF hub, the BCM, the IC, the CAN data bus or the electronic communication related to remote start indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

SEAT BELT INDICATOR

The seat belt indicator gives an indication to the vehicle operator of the status of the driver side front seat belt (export market vehicles) or driver and passenger front seat

belts (domestic market vehicles). This indicator is controlled by a transistor on the IC circuit board based upon programming and electronic messages received over the CAN data bus from the ORC.

The seat belt indicator also includes a programmable enhanced seat belt reminder or BELTMINDER feature that is enabled when the vehicle is shipped from the factory. This BELTMINDER feature can be disabled and enabled by the customer using a specific programming event sequence, or by the dealer using a diagnostic scan tool.

The seat belt indicator LED is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the LED will always be OFF when the ignition switch status is anything except ON or START. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the seat belt indicator for the following reasons:

- **Seat Belt Reminder Function** - Each time the IC receives a battery current input on the fused ignition switch (run-start) circuit, the indicator will be illuminated as a seat belt reminder for about six seconds, or until the ignition switch status transitions to OFF, whichever occurs first. This reminder function will occur regardless of the status of the seat belt switch input to the ORC.
- **Front Seat Belt Not Buckled - Beltminder Active** - Following the seat belt reminder function, each time the IC receives an electronic **seat belt indicator lamp-On** message from the ORC while the ignition switch status is START or ON, the indicator will be illuminated. In addition, if the front seat belt remains unbuckled about 18 to 25 seconds after the conclusion of the seat belt reminder function with the vehicle speed greater than about 8 kilometers-per-hour (5 miles-per-hour), the seat belt indicator will begin to cycle between flashing ON and OFF for 3 seconds, then lighting solid for 2 seconds. The seat belt indicator will continue to cycle between flashing and solid illumination for 13 complete cycles, until the seat belt switch sense inputs to the ORC are closed circuits (seat belt switch closed = seat belt buckled), or until the ignition switch status transitions to OFF, whichever occurs first.
- **Front Seat Belt Not Buckled - Beltminder Inactive** - Following the seat belt reminder function, each time the IC receives an electronic **seat belt indicator lamp-On** message from the ORC while the ignition switch status is START or ON, the indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the ORC or until the ignition switch status transitions to OFF, whichever occurs first.

Each seat belt switch is connected in series between source current and a sense circuit from the ORC. The ORC continually monitors the seat belt switch circuits then sends the proper lamp-on or lamp-off messages to the IC. The seat belt switch inputs to the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. For proper diagnosis of the ORC, the IC, the CAN data bus or the electronic communication related to seat belt indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

SECURITY INDICATOR

The security indicator gives an indication to the vehicle operator when the Vehicle Theft Security System (VTSS) is arming or is armed. On vehicles equipped with the Sentry Key Immobilizer System (SKIS), the security indicator also gives an indication to the vehicle operator of the status of the SKIS. This indicator is controlled by a transistor on the IC circuit board based upon a hard wired input to the IC from the BCM and electronic messages received by the BCM from the RF hub over the CAN data bus. The BCM will illuminate the security indicator for about three seconds as a bulb test each time the ignition switch status transitions to ON.

The security indicator LED is completely controlled by the BCM logic circuit, and that logic will allow this indicator to operate whenever the BCM receives a battery current input on the fused B(+) circuit. Therefore, the LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the BCM. Depending upon the programmed condition the indicator can be illuminated solid, flashed at a slow rate (0.5 Hertz, 12.5 percent duty cycle), or flashed at a fast rate (1 Hertz, 50 percent duty cycle). The IC will turn ON the security indicator for the following reasons:

- **VTSS Indication** - During the 16 second VTSS arming function, the BCM will flash the security indicator ON and OFF repeatedly at a steady, fast rate to indicate that the VTSS is in the process of arming. Following successful VTSS arming, the BCM flashes the security indicator ON and OFF continuously at a slower rate to indicate that the VTSS is armed. The security indicator continues flashing at the slower rate until the VTSS is disarmed or triggered. If the VTSS has alarmed and rearmed, the BCM will flash the security indicator at a steady, slow rate for about 30 seconds after the VTSS is disarmed.
- **SKIS Indicator Lamp-On Message** - Each time the BCM receives an electronic **SKIS indicator lamp-ON** message from the RF hub, the security indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the RF hub message. The indicator remains illuminated solid or continues to flash until the BCM receives a lamp-OFF message from the RF hub, or until the ignition switch status transitions to OFF, whichever occurs first. For more information on the SKIS and the security indicator control parameters, (Refer to 08 - Electrical/8Q - Vehicle Theft Security - Operation) .
- **SKIS Textual Message** - When the RF hub detects certain monitored conditions or is placed in the programming mode it will send electronic messages requesting the IC display textual messages, and the appropriate textual message or combination of messages is illuminated in the electronic display unit. **PROGRAMMING ACTIVE**, **NEW KEY PROGRAMMED**, **REMOTE KEY BATTERY LOW** and **SERVICE SECURITY KEY** messages appear individually, while a **KEY NOT PROGRAMMED** message is followed by either a **DAMAGED KEY**, **INVALID KEY** or **EXCEEDED KEY PROGRAM LIMIT** message and an **INVALID KEY** message is followed by a **TRY ALTERNATE KEY** message. The textual messages related to key programming are active only on vehicles sold in markets where customer programming is an available feature of the SKIS.
- **Communication Error** - If the BCM receives no lamp-ON or lamp-OFF messages from the RF hub for 10 consecutive message cycles, the security indicator is illuminated by the BCM. The indicator remains controlled and illuminated by the BCM until a valid lamp-ON or lamp-OFF message is received from the RF hub.

The BCM circuitry controls the security indicator whenever the ignition switch status is OFF and the VTSS is arming, armed, or alarming. Whenever the ignition switch status is ON or START, RF hub performs a self-test to decide whether the SKIS is in good operating condition and whether a valid key is present within the vehicle. The RF hub then sends the proper lamp-ON or lamp-OFF message to the BCM. If the BCM flashes the security indicator when the ignition switch transitions to ON, or turns ON the security indicator solid after the bulb test, it indicates that a SKIS malfunction has occurred or that the SKIS is ineffective.

For proper diagnosis of the VTSS, the SKIS, the BCM, the RF hub, the IC, the CAN data bus or the electronic communication related to security indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

SERVICE COLUMN LOCK INDICATOR

The service column lock indicator gives an indication to the vehicle operator when the RF hub has recorded a DTC for a steering column shaft lock module circuit or component malfunction. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received by the IC from the RF hub over the CAN data bus.

The service column lock indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the service column lock indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the service column lock indicator for the following reasons:

- **Service Column Lock Indicator Lamp-On Message** - Each time the IC receives an electronic **service column lock indicator lamp-ON** message from the RF hub, the service column lock indicator will be illuminated. The indicator remains illuminated for about five seconds, until the IC receives a lamp-OFF message from the RF hub, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first.

The RF hub continually monitors the steering column shaft lock module circuits and components to determine the condition of the system. The RF hub then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the shaft lock module, the RF hub, the IC, the CAN data bus or the electronic communication related to service column lock indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

TRACTION CONTROL INDICATOR

The traction control indicator gives an indication to the vehicle operator when the ESC/BAS/Traction Control System (TCS) has been activated. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received by the IC from the CAB over the CAN data bus. The IC will illuminate the traction control indicator for about four seconds as a bulb test each time the ignition switch status transitions to ON.

The traction control indicator is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the indicator will always be OFF when the ignition switch status is anything except ON or START. The indicator only illuminates when it is provided a path to ground by the IC circuitry. The IC will turn ON the traction control indicator for the following reasons:

- **Traction Control Indicator Lamp-On Message** - Each time the IC receives an electronic **traction control indicator lamp-ON** message from the CAB indicating that the ESC/BAS/TCS has been activated, the traction control indicator will be illuminated. The indicator can be flashed ON and OFF, or illuminated solid, as dictated by the CAB message. The indicator remains illuminated solid or continues to flash until the IC receives a lamp-OFF message from the CAB, or until the ignition switch status transitions to OFF, whichever occurs first.

The CAB continually monitors the traction control switch to determine the proper outputs to the components of the Antilock Brake System (ABS). The CAB then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the traction control switch, the ESC/BAS/TCS, the CAB, the IC, the CAN data bus or the electronic communication related to traction control indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

TRANSMISSION TEMPERATURE INDICATOR

The transmission over-temperature indicator gives an indication to the vehicle operator when the transmission fluid temperature is excessive, which may lead to accelerated transmission component wear or failure. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received over the CAN data bus from the TCM.

The transmission over-temperature indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the transmission over-temperature indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the transmission over-temperature indicator for the following reasons:

- **Trans Over-Temp Indicator Lamp-On Message** - Each time the IC receives an electronic **trans over-temp indicator lamp-ON** message from the TCM indicating that the fluid temperature is too high, the transmission over-temperature indicator will be illuminated and a single chime tone is sounded. The indicator remains illuminated for about five seconds, until the IC receives a lamp-OFF message from the TCM, until the IC arbitrator logic determines that another display request has priority, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the indicator is cycled OFF and then ON again by the appropriate lamp-ON and lamp-OFF messages from the TCM.

The TCM continually monitors the transmission temperature sensor to determine the transmission operating condition. The TCM then sends the proper lamp-ON or lamp-OFF message to the IC. If the IC illuminates the transmission over-temperature indicator due to a high transmission oil temperature condition, it may indicate that the transmission or the transmission cooling system are being overloaded or that they require service.

For proper diagnosis of the transmission temperature sensor, the TCM, the IC, the CAN data bus or the electronic communication related to transmission over-temperature indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

TURN SIGNAL INDICATORS

The turn signal indicators give an indication to the vehicle operator that the turn signal (left or right indicator flashing) or hazard warning (both left and right indicators flashing) have been selected and are operating. These indicators are controlled by transistors on the IC cluster electronic circuit board based upon cluster programming and electronic messages received from the BCM over the CAN data bus.

Each turn signal indicator Light Emitting Diode (LED) unit is completely controlled by the IC logic circuit, and that logic will allow this indicator to operate whenever the IC receives a battery current input on the fused B(+) circuit. Therefore, each LED can be illuminated regardless of the ignition switch status. The LED only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the turn signal indicators for the following reasons:

- **Turn Signal Indicator Lamp-On Message** - Each time the IC receives an electronic **right** or **left turn signal indicator lamp-On** message from the BCM over the CAN data bus, the appropriate turn signal indicator will be flashed on and off. The BCM messages to the IC also control the flash rate of the turn signal indicators, as well as the click rate of an electromechanical relay soldered onto the IC electronic circuit board that emulates the sound emitted by a conventional turn signal flasher. The turn signal indicators continue to flash on and off until the IC receives a lamp-OFF message from the BCM, or until the ignition switch status transitions to OFF, whichever occurs first.
- **Hazard Warning Indicator Lamp-On Message** - Each time the IC receives an electronic **hazard warning indicator lamp-On** message from the BCM over the CAN data bus, both turn signal indicators will be flashed on and off. The BCM messages to the IC also control the flash rate of the turn signal indicators, as well as the click rate of an electromechanical relay soldered onto the IC electronic circuit board that emulates the sound emitted by a conventional hazard warning flasher. The turn signal indicators continue to flash on and off until the IC receives a lamp-OFF message from the BCM.
- **Turn Signal-On Textual Warning Message** - When the BCM detects that a turn signal has been active continuously for 1.6 kilometers (1 mile) with the vehicle speed greater than 22 kilometers-per-hour (15 miles-per hour) a **TURN SIGNAL ON** textual message and flashing right or left turn signal icon will appear within the IC electronic display unit and a chime tone will be sounded.
- **Lamp Out Mode** - If the BCM detects an ineffective turn signal lamp or circuit, it increases the flash rate for the remaining operative turn signals and sends an electronic message to the IC. The IC then increases the flash rate of the turn signal indicators and the click rate of the electromechanical relay to provide an indication of the problem to the vehicle operator.

The IC continually monitors electronic messages from the BCM to determine the proper turn signal and hazard warning indicator operation.

For proper diagnosis of the turn signal and hazard warning system, the multi-function switch, the BCM, the IC, the CAN data bus or the electronic communication related

to turn signal indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

WAIT-TO-START INDICATOR

The wait-to-start indicator gives an indication to the vehicle operator when the diesel engine is too cool for efficient and reliable engine starting, and the engine glow plugs are energized in their preheat operating mode. This indicator is controlled by a transistor on the IC electronic circuit board based upon programming and electronic messages received by the IC from the ECM over the CAN data bus.

The wait-to-start indicator is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the indicator will always be OFF when the ignition switch status is anything except ON or START. The icon only illuminates when it is provided a path to ground by the IC transistor. The IC will turn ON the wait-to-start indicator for the following reasons:

- **Wait-To-Start Indicator Lamp-On Message** - Each time the IC receives an electronic **wait-to-start indicator lamp-ON** message from the ECM indicating that the air temperature is too cool for efficient and reliable engine starting and the glow plugs are energized in their preheat mode, the wait-to-start indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the ECM, until the ECM detects that the engine is running, or until the ignition switch status transitions to OFF, whichever occurs first.

The ECM continually monitors the glow plug control circuits to determine when they are energized in their preheat operating mode. The ECM then sends the proper lamp-ON or lamp-OFF message to the IC. For proper diagnosis of the wait-to-start indicator, the ECM, the IC, the CAN data bus or the electronic communication related to wait-to-start indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

WASHER FLUID INDICATOR

The washer fluid indicator gives an indication to the vehicle operator that the fluid level in the washer reservoir is low. This indicator is controlled by the IC logic circuit based upon programming and electronic messages received from the BCM over the CAN data bus.

The washer fluid indicator function of the electronic display unit is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the washer fluid indication will always be OFF when the ignition switch status is anything except ON or START. The IC will turn ON the washer fluid indicator for the following reasons:

- **Washer Fluid Indicator Lamp-On Message** - Each time the IC receives an electronic **washer fluid indicator lamp-ON** message from the BCM indicating that a low washer fluid condition has been detected for 60 consecutive seconds, the washer fluid indicator is illuminated and a single chime tone is sounded. The indicator remains illuminated until the IC receives lamp-OFF messages for 60 consecutive seconds from the BCM, or until the ignition switch status transitions to OFF, whichever occurs first. The chime tone feature will only repeat during the same ignition cycle if the washer fluid indicator is cycled OFF and then ON again by the appropriate lamp-ON and lamp-OFF messages from the BCM.

The BCM continually monitors the washer fluid level switch in the washer reservoir to determine the level of the washer fluid. The BCM then sends the proper lamp-ON or lamp-OFF message to the IC.

For proper diagnosis of the washer fluid level switch, the BCM, the IC, the CAN data bus or the electronic communication related to washer fluid indicator operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

WATER-IN-FUEL INDICATOR

The water-in-fuel indicator gives an indication to the vehicle operator when there is excessive water in the fuel system. This indicator is controlled by the IC based upon programming and electronic messages received from the ECM over the Controller Area Network (CAN) data bus.

The water-in-fuel indicator is completely controlled by the IC logic circuit, and that logic will only allow this indicator to operate when the IC receives a battery current input on the fused ignition output (run-start) circuit. Therefore, the indicator will always be OFF when the ignition switch status is anything except ON or START. The icon only illuminates when it is provided a path to ground by the IC transistor. Each time the ignition switch status transitions to ON the water-in-fuel indicator is illuminated for about two seconds as a bulb test. The water-in-fuel indicator will be turned ON for the following reasons:

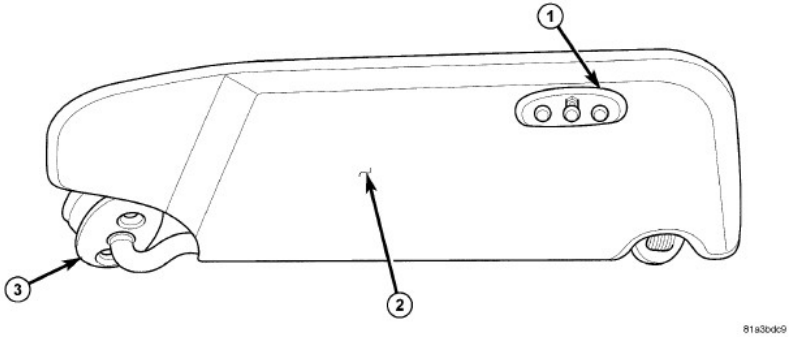
- **Water-In-Fuel Indicator Lamp-On Message** - Each time the IC receives an electronic **water-in-fuel lamp-ON** message from the ECM indicating that there is excessive water in the diesel fuel system, the water-in-fuel indicator will be illuminated. The indicator remains illuminated until the IC receives a lamp-OFF message from the ECM, or until the ignition switch status transitions to OFF, whichever occurs first.

The ECM continually monitors the water-in-fuel sensor to determine whether there is excessive water in the diesel fuel system. The ECM then sends the proper lamp-ON or lamp-OFF message to the IC. For proper diagnosis of the water-in-fuel operation a diagnostic scan tool is required. Refer to the appropriate diagnostic information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION



Some vehicles are equipped with the HomeLink® transceiver (1). The transceiver is located in the driver side sun visor assembly (2). The only visible component of the HomeLink® transceiver are the three push buttons. The buttons are marked with one, two or three dots, respectively, for identification of each channel.

Each of the three HomeLink® transceiver push buttons controls an independent radio transmitter channel. Each of these three channels can be trained to transmit a different radio frequency signal for the remote operation of garage door openers, motorized gate openers, home or office lighting, security systems or just about any other device that can be equipped with a radio receiver in the 280 to 418 MegaHertz (MHz) frequency range for remote operation. The transceiver is capable of operating systems using either rolling code or non-rolling code technology. The system will not transmit operating signals if the Vehicle Theft Security System is armed.

The HomeLink® transceiver cannot be repaired, and is available for service only with the visor assembly. If any part of the component is inoperative or damaged, the complete visor assembly must be replaced, (Refer to 23 - Body/Interior/VISOR - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The HomeLink® transceiver operates on a direct battery feed so the unit will remain functional, regardless of the ignition switch position. The transceiver has a security ground and will become disabled any time the vehicle security alarm is armed. For more information on the features, programming procedures and operation of the HomeLink® transceiver, see the owner's manual in the vehicle glove box.

ERASING HOMELINK® TRANSCEIVER CODES

NOTE: Individual channels cannot be erased. Erasing the HomeLink® transceiver codes will erase ALL programmed codes.

To erase programming from all three buttons (individual buttons cannot be erased but can be "reprogrammed"), follow the step noted:

- Press and hold the two outer HomeLink® transceiver buttons until the indicator light begins to flash-after 20 seconds. Release both buttons. Do not hold for longer that 30 seconds. HomeLink® is now in the train (or learning) mode and can be programmed at any time beginning with "Programming" (Refer to 08 - Electrical/8M - Message Systems/Universal Transmitter - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

PROGRAMMING HOMELINK® TRANSCEIVER CODES

WARNING: **Vehicle exhaust contains carbon monoxide, a dangerous gas. Do not run the engine while training the universal transmitter. Failure to follow these instructions may result in possible serious or fatal injury.**

WARNING: **Your motorized door or gate may open and close while you are training the universal transmitter if the vehicle is in range of the motorized device. Do not train the universal transmitter if people or pets are in the path of the door or gate. A moving door or gate can cause serious injury or death to people and pets or damage to objects.**

NOTE: When programming a garage door opener, it is advised to park outside the garage. It is also recommended that a new battery be placed in the hand-held transmitter of the device being programmed to the HomeLink® transceiver for quicker training and accurate transmission of the radio-frequency signal.

NOTE: If programing the HomeLink® transceiver is unsuccessful using the following procedure, refer to the Owner's Manual for the current customer assistance phone number.

1. Press and hold the two outer HomeLink® transceiver buttons, and release only when the indicator light begins to flash (after 20 seconds). **Do not** hold the buttons for longer than 30 seconds and **do not** repeat step one to program a second and/or third hand-held transmitter to the remaining two HomeLink® transceiver buttons.

2. Position the end of your hand-held transmitter 3-8 cm (1-3 inches) away from the HomeLink® transceiver buttons while keeping the indicator light in view.

3. Simultaneously press and hold both the HomeLink® transceiver button that you want to train and the hand-held transmitter button. **Do not release the buttons until step 4 has been completed.**

   NOTE: Some gate operators and garage door openers may require you to replace this Programming Step 3 with procedures noted in the "Gate Operator/Canadian Programming" section.

4. The HomeLink® transceiver indicator light will flash slowly and then rapidly after HomeLink® successfully receives the frequency signal from the hand-held transmitter. Release both buttons after the indicator light changes from the slow to rapid flash.

5. Press and hold the just trained HomeLink® transceiver button and observe the indicator light. If the indicator light **stays on constantly, programming is complete** and your device should activate when the button is pressed and released.

   NOTE: To program the remaining two buttons, begin with "Programming" step 2. Do not repeat step 1.

   If the indicator light blinks rapidly for two seconds and then turns to a constant light, continue with "Programming" steps 6-8 to complete the programming of a rolling code equipped device (most commonly a garage door opener).

6. At the garage door opener receiver (motor-head unit) in the garage, locate the "learn" or "smart" button. This can usually be found where the hanging antenna wire is attached to the motor-head unit.

7. Firmly press and release the "learn" or "smart" button. (The name and color of the button may vary by manufacturer.)

   NOTE: There are 30 seconds in which to initiate step 8.

8. Return to the vehicle and firmly **press, hold for two seconds and release** the programmed HomeLink® transceiver button. Repeat the **"press/hold/release"** sequence a second time, and, depending on the brand of the garage door opener (or other rolling code equipped device), repeat this sequence a third time to complete the programming. The HomeLink® transceiver should now activate your rolling code equipped device.

NOTE: To program the remaining two HomeLink® transceiver buttons, begin with "Programming" step 2. Do not repeat step 1.

Canadian Programming/Gate Programming

Canadian radio-frequency laws require transmitter signals to "time-out" (or quit) after several seconds of transmission which may not be long enough for the HomeLink® transceiver to pick up the signal during programming. Similar to this Canadian law, some U.S. gate operators are designed to "time-out" in the same manner.

If you live in Canada or you are having difficulties programming a gate operator by using the "Programming" procedures (regardless of where you live), **replace "Programming HomeLink® Transceiver Codes" step 3** with the following:

NOTE: When programming a garage door opener or gate operator, it is advised to unplug the device or move the vehicle out of range during the "cycling" process to prevent possible overheating.

3. Continue to press and hold the HomeLink® transceiver button while you **press and release every two seconds** ("cycle") your hand-held transmitter until the frequency signal has successfully been accepted. The indicator light will flash slowly and then rapidly. Proceed with "Programming" step 4 to complete.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

REPROGRAMMING HOMELINK® TRANSCEIVER CODES

WARNING: **Vehicle exhaust contains carbon monoxide, a dangerous gas. Do not run the engine while training the universal transmitter. Failure to follow these instructions may result in possible serious or fatal injury.**

WARNING: **Your motorized door or gate may open and close while you are training the universal transmitter if the vehicle is in range of the motorized device. Do not train the universal transmitter if people or pets are in the path of the door or gate. A moving door or gate can cause serious injury or death to people and pets or damage to objects.**

NOTE: If programing the HomeLink® transceiver is unsuccessful using the following procedure, refer to the Owner's Manual for the current customer assistance phone number.

To program a device to the HomeLink® transceiver using a button previously trained, follow these steps:

1. Press and hold the desired HomeLink® transceiver button. **DO NOT** release the button. The indicator light will begin to flash after 20 seconds. Without releasing the HomeLink® transceiver button, proceed to step 2.
2. Position the end of your hand-held transmitter 3-8 cm (1-3 inches) away from the HomeLink® transceiver button while keeping the indicator light in view.
3. Simultaneously press and hold both the HomeLink® transceiver button that you want to train and the hand-held transmitter buttons. **Do not release the buttons until step 4 has been completed.**

   NOTE: Some gate operators and garage door openers may require you to replace this Reprogramming Step 3 with procedures noted in the "Gate Operator/Canadian Programming" section.
4. The HomeLink® transceiver indicator light will flash slowly and then rapidly after it successfully receives the frequency signal from the hand-held transmitter. Release both buttons after the indicator light changes from the slow to the rapid flash.
5. Press and hold the just trained HomeLink® transceiver button and observe the indicator light. If the indicator light **stays on constantly, reprogramming is complete** and your device should activate when the button is pressed and released.

   NOTE: If the indicator light blinks rapidly for two seconds and then turns to a constant light, continue with "Reprogramming" steps 6-8 to complete the programming of a rolling code equipped device (most commonly a garage door opener).
6. At the garage door opener receiver (motor-head unit) in the garage, locate the "learn" or "smart" button. This can usually be found where the hanging antenna wire is attached to the motor-head unit.
7. Firmly press and release the "learn" or "smart" button. (The name and color of the button may vary by manufacturer.)

   NOTE: There are 30 seconds in which to initiate step 8.
8. Return to the vehicle and firmly **press, hold for two seconds and release** the reprogrammed HomeLink® transceiver button. Repeat the **"press/hold /release"** sequence a second time, and, depending on the brand of the garage door opener (or other rolling code equipped device), repeat this sequence a third time to complete the reprogramming. The HomeLink® transceiver should now activate your rolling code equipped device.

Canadian Programming/Gate Programming

Canadian radio-frequency laws require transmitter signals to "time-out" (or quit) after several seconds of transmission which may not be long enough for the HomeLink® transceiver to pick up the signal during programming. Similar to this Canadian law, some U.S. gate operators are designed to "time-out" in the same manner.

If you live in Canada or you are having difficulties programming a gate operator by using the "Programming" procedures (regardless of where you live), **replace "Reprogramming HomeLink® Transceiver Codes" step 3** with the following:

NOTE: When programming a garage door opener or gate operator, it is advised to unplug the device or move the vehicle out of range during the "cycling" process to prevent possible overheating.

3. Continue to press and hold the HomeLink® transceiver button while you **press and release every two seconds** ("cycle") your hand-held transmitter until the frequency signal has successfully been accepted. The indicator light will flash slowly and then rapidly. Proceed with "Programming" step 4 to complete.

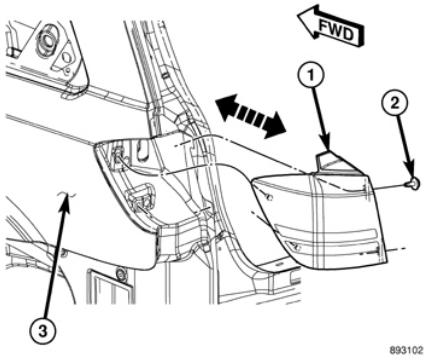
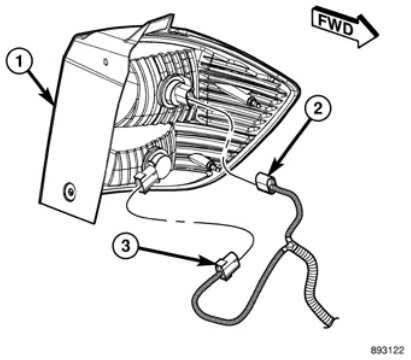
STANDARD PROCEDURE - TRAILER TOW HARNESS INSTALLATION

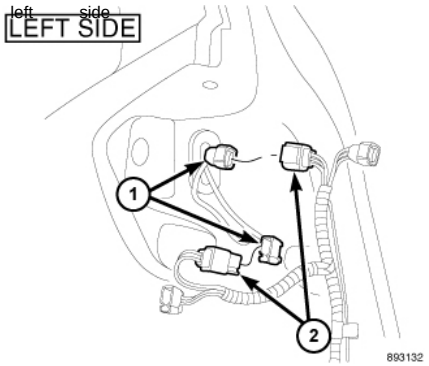
1. Remove the push pin fasteners (2) and separate the rear tail lamp assemblies (1).



2. Disconnect the tail lamp electrical connectors (2 and 3).

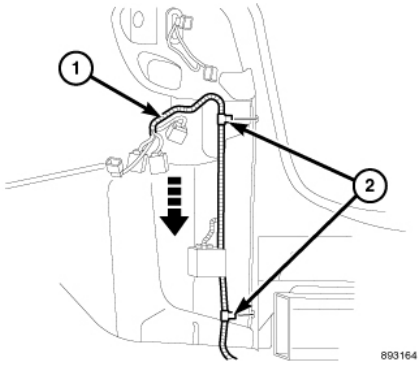


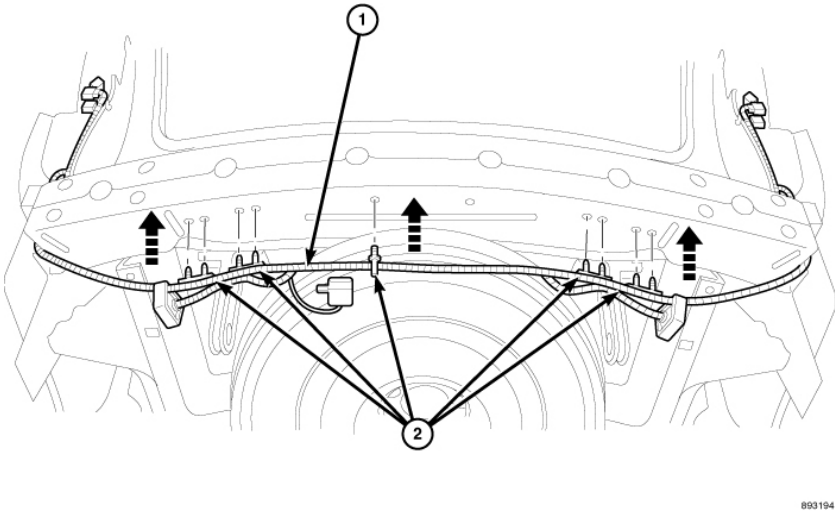
3. Connect the harness (2) to the left side tail lamp electrical connectors (1).



4. Position the harness (1) through the tail lamp opening and down the side of the fender.

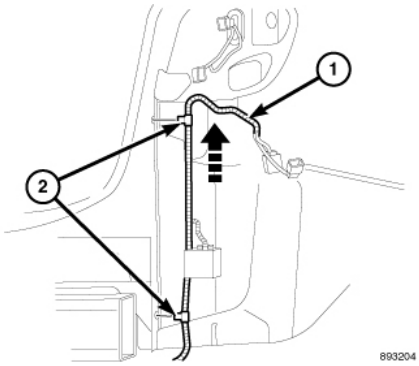
5. Secure the support clips (2) to the body seem.



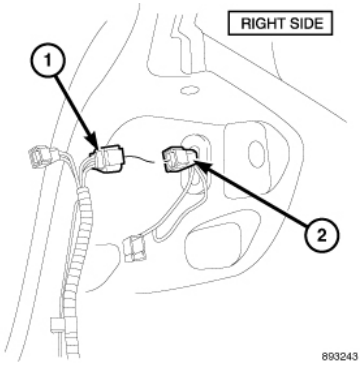


6. Position the harness (1) over the exhaust and fasten the push pin fasteners (2) to the under side of the rear bumper in the existing holes.

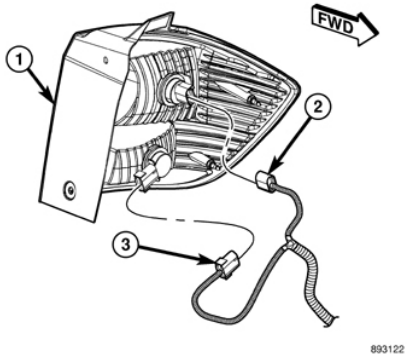
7. Position the harness (1) up the right side of the vehicle to the right tail lamp opening and secure the clips (2) to the body seem.



8. Connect the harness (1) to the right side tail lamp electrical connectors (2).



9. Connect the tail lamp electrical connectors (2 and 3) to the tail lamp assemblies (1).



10. Install tail lamps assemblies (1) and install the push pin fasteners (2) fully.

WARNING

WARNING:

Chrysler LLC does not manufacture any vehicles or replacement parts that contain asbestos. Aftermarket products may or may not contain asbestos. Refer to aftermarket product packaging for product information.

Whether the product contains asbestos or not, dust and dirt can accumulate on brake parts during normal use. Follow practices prescribed by appropriate regulations for the handling, processing and disposing of dust and debris.

WARNING:

Do not remove the strut rod nut while strut assembly is installed in vehicle, or before the coil spring is compressed with a compression tool. The spring is held under high pressure.

CAUTION:

At no time when servicing a vehicle can a sheet metal screw, bolt, or other metal fastener be installed in the shock tower to take the place of an original plastic clip. It may come into contact with the strut or coil spring.

CAUTION:

Wheel bearing damage will result if after loosening the axle hub nut, the vehicle is rolled on the ground or the weight of the vehicle is allowed to be supported by the tires for any length of time.

WARNING

WARNING: The A/C system contains refrigerant under high pressure. Repairs should only be performed by qualified service personnel. Serious or fatal injury may result from improper service procedures.

WARNING: Avoid breathing the refrigerant and refrigerant oil vapor or mist. Exposure may irritate the eyes, nose, and/or throat. Wear eye protection when servicing the A/C refrigerant system. Serious eye injury can result from direct contact with the refrigerant. If eye contact occurs, seek medical attention immediately.

WARNING: Do not expose the refrigerant to open flame. Poisonous gas is created when refrigerant is burned. An electronic leak detector is recommended. Serious or fatal injury may result from improper service procedures.

WARNING: If accidental A/C system discharge occurs, ventilate the work area before resuming service. Large amounts of refrigerant released in a closed work area will displace the oxygen and cause suffocation and serious or fatal injury.

WARNING: The evaporation rate of R-134a refrigerant at average temperature and altitude is extremely high. As a result, anything that comes in contact with the refrigerant will freeze. Always protect the skin or delicate objects from direct contact with the refrigerant.

WARNING: The R-134a service equipment or the vehicle refrigerant system should not be pressure tested or leak tested with compressed air. Some mixtures of air and R-134a have been shown to be combustible at elevated pressures. These mixtures are potentially dangerous, and may result in fire or explosion causing property damage and serious or fatal injury.

WARNING: The engine cooling system is designed to develop internal pressures up to 145 kPa (21 psi). Do not remove or loosen the coolant pressure cap, cylinder block drain plugs, radiator drain, radiator hoses, heater hoses, or hose clamps while the engine cooling system is hot and under pressure. Allow the vehicle to cool for a minimum of 15 minutes before opening the cooling system for service. Failure to observe this warning can result in serious burns from the heated engine coolant.

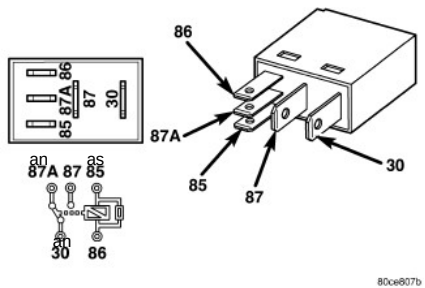
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Vehicles equipped with an optional trailer tow preparation package have three trailer tow relays, one each for the trailer tow stop/turn right and left and one for the trailer park lamps. The trailer tow relays are conventional International Standards Organization (ISO) micro relays. Relays conforming to the ISO specifications have common physical dimensions, current capacities, terminal patterns, and terminal functions. Each relay is contained within a small, rectangular, molded plastic housing and is connected to all of the required inputs and outputs through five integral male spade-type terminals that extend from the relay base plate.



The trailer tow relays are included with the trailer tow preparation wire harness that is shipped loose in the glove box for customer or dealer installation at the rear of the vehicle. The relays are located behind the rear fascia and below the rear bumper reinforcement. Each relay and connector is wrapped within an isolator envelope for sound deadening and anti-rattle protection. Refer to the appropriate wiring information for specific relay cavity assignment information.

Any of the trailer tow relays cannot be adjusted or repaired and, if ineffective or damaged, the affected unit must be replaced.

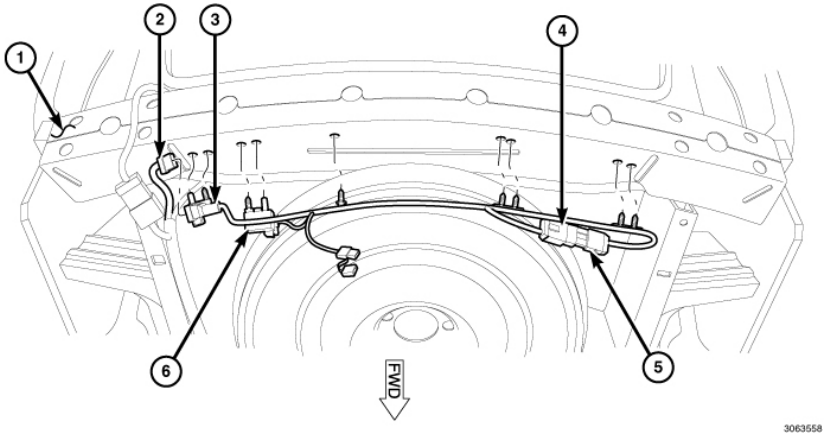
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure



NOTE: There are three relays included with the trailer tow preparation wiring kit. They are: the trailer tow right stop/turn relay (4), the trailer tow left stop/turn relay (5) and the trailer tow park lamps relay (6). The service procedures for all three relays are the same.

1. Align the terminals of the trailer tow right stop/turn relay (4), the trailer tow left stop/turn relay (5) or the trailer tow park lamps relay (6) with the terminal receptacles of the trailer tow wire harness (3) relay connector secured to the underside of the rear bumper reinforcement (1).
2. Firmly and evenly push the relay into the connector until it is fully seated.
3. Reinstall the rear fascia onto the vehicle. (Refer to 13 - Frame and Bumpers/Bumpers/FASCIA, Rear - Installation) .
4. Reconnect the battery negative cable.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The trailer tow relays are electromechanical switches that use a low current input from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) to the tail lamps to control a high current output to either the trailer park lamps or the right or left trailer brake and turn signal lamps. Within each relay are an electromagnetic coil, a movable contact and two fixed contact points. A resistor is connected in parallel with the coil, and helps to dissipate voltage spikes and electromagnetic interference that can be generated as the field of the relay coil collapses.

The movable common supply contact point is held against the fixed normally closed contact point by spring pressure. When the relay coil is energized, an electromagnetic field is produced by the coil windings. This field draws the movable contact away from the normally closed contact, and holds it against the normally open contact. When the relay coil is de-energized, spring pressure returns the movable contact back against the normally closed contact.

The inputs and outputs of the trailer tow relays include:

- **Common Supply Terminal (30)** - The common feed terminal of both the left and right trailer tow stop/turn relays is connected to their respective left or right trailer tow stop/turn signal pins of the 4-way trailer tow connector at all times. The common feed terminal of the trailer tow park lamps relay is connected to the trailer tow park lamps pin of the 4-way trailer tow connector at all times.
- **Coil Ground Terminal (85)** - The coil ground terminal of both the left and right trailer tow stop/turn relays is connected to a fused B(+) circuit at all times. The coil ground terminal of the trailer tow park lamps relay is also connected to a fused B(+) circuit at all times.
- **Coil Battery Terminal (86)** - The coil battery terminal of both the left and right trailer tow stop/turn relays is connected to their respective left or right trailer tow stop/turn relay control circuits from the BCM at all times. The coil battery terminal of the trailer tow park lamps relay is connected to the trailer tow park lamps relay control from the BCM at all times.
- **Normally Open Terminal (87)** - The normally open terminal of both the left and right trailer tow stop/turn relays is connected to a fused B(+) circuit at all times. The normally open terminal of the trailer tow park lamps relay is also connected to a fused B(+) circuit at all times.
- **Normally Closed Terminal (87A)** - The normally closed terminal of all three trailer tow relays are connected to their respective common supply (30) terminals whenever the relay is de-energized. The normally closed terminals of the trailer tow relays are not connected to any circuit in this application.

The trailer tow relays and the hard wired circuits for the relays may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between other modules and devices that provide some features of the trailer tow stop/turn and park lamps lighting system. The most reliable, efficient, and accurate means to diagnose the electronic controls and communication related to trailer tow stop/turn and park lamps lighting operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

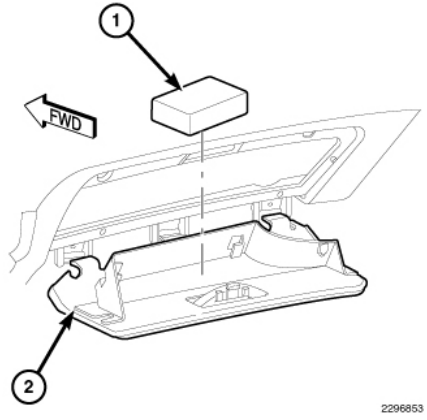
DESCRIPTION

Vehicles equipped with an optional Trailer Tow Preparation package have a trailer tow wiring harness and an instruction sheet (1) that are placed in the glove box (2) of the vehicle when it is shipped from the factory. This package also includes relays to isolate the trailer lighting from the vehicle lighting and a four-way trailer tow wiring connector that are all concealed behind the rear bumper fascia after installation is complete.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The trailer tow preparation wiring harness is connected to the body wire harness near the left side of the spare tire, just forward of the rear bumper reinforcement. After installation is complete, a trailer tow right stop/turn relay, a trailer tow left stop/turn relay and a trailer tow park lamps relay are secured to the trailer tow harness on the underside of the rear bumper reinforcement behind the rear fascia. The four-way trailer tow connector is located near the center of the rear fascia.

Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds. Also refer to the Instruction Sheet packaged with the harness for additional details.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The navigation system offers several new customer features for expanded usability and convenience with hands-free voice-activated operation in addition to the touch screen buttons. The navigation system uses the Bluetooth microphone in the rear view mirror. Navigation routes can be based on a variety of formats including some of the following:

- Destination entry by street intersection, city, zip code, street name, street address and number, state/province/country and phone number
- Stop/change route
- Save current position
- Personal menu, including Guide Me Home (Go Home), Trip Itinerary, List of Saved Locations, Favorite Points of Interest (from a data base), Manage Personal User and Choose User
- Personal Interests including recent routes, address book, Where Am I Now, Emergency (police stations, Dodge dealerships, fire stations, hospitals and emergency care centers), Trail and geographic coordinates
- Route options include shortest, quickest, maximize freeways, minimize freeways, avoid toll roads and avoid ferries
- Navigation can be put into DEMO mode to enhance trip planning

This navigation system will support Traffic Messaging. Traffic Messaging displays voice and pop up warning messages for medium and high priority situations on the route such as road closures due to accidents/hazardous situations and it can even generate a traffic detour for a traffic event located on the route.

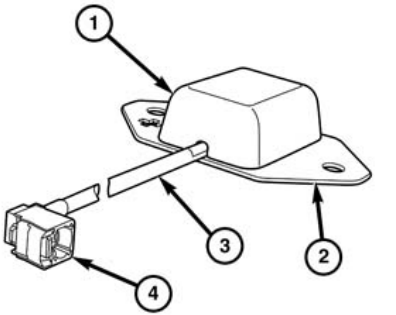
DESCRIPTION

In vehicles equipped with the navigation system and the optional satellite audio feature the navigation antenna has been integrated into the satellite antenna on the roof of the vehicle. (Refer to 08 - Electrical/8A - Audio and Video/ANTENNA, Satellite - Description) . In vehicles equipped with the navigation system, but not equipped with the optional satellite audio feature, a dedicated navigation antenna module (1) is used.

The dedicated navigation antenna module is located on the top of the instrument panel base trim near the windshield and adjacent to the sun load sensor. The navigation antenna module has a stamped metal mounting flange (2) that is secured to the instrument panel base trim by two screws. A single pigtail cable (3) with an integral connector (4) exits the antenna module and is routed down through the instrument panel to the navigation unit, which is integral to the Radio Receiver Module (RRM) (also known as the radio or the head unit). The antenna module, its mounting and the cable are all concealed beneath the defroster grille on the top of the instrument panel.

The dedicated navigation antenna module cannot be adjusted or repaired. If damaged or ineffective the entire unit must be replaced.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

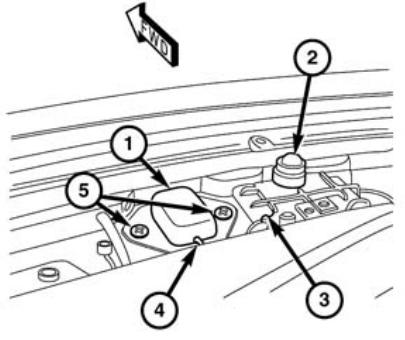
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

In vehicles equipped with the optional satellite radio system, the navigation antenna is serviced as a unit with the combination antenna located on the roof panel. (Refer to 08 - Electrical/8A - Audio and Video/ANTENNA, Satellite/Installation) .

1. Position the navigation antenna module (1) onto the top of the instrument panel base trim (3) adjacent to the sun load sensor (2).
2. Install and tighten the two screws (5) that secure the navigation antenna module mounting flange to the instrument panel base trim. Tighten the screws securely.
3. Route the navigation antenna module cable (3) down through the instrument panel and connect it to the Radio Receiver Module (RRM) (also known as the radio or the head unit).
4. Reinstall the RRM into the instrument panel. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Telematics Gateway/Installation) .



0819003723

5. Reinstall the defroster grille onto the top of the instrument panel. (Refer to 23 - Body/Instrument Panel/GRILLE, Defroster/Installation) .
6. Reconnect the negative cable to the battery.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The navigation module acquires Global Positioning System (GPS) position data through a navigation antenna module. Vehicles equipped with the optional satellite radio system have a roof-mounted combination antenna that also receives satellite audio and cellular signals. (Refer to 08 - Electrical/8A - Audio and Video/ANTENNA, Satellite/Description) . Vehicles not equipped with the optional satellite radio system have a dedicated navigation antenna module mounted on the top of the instrument panel near the windshield.

The navigation antenna module is used to provide satellite information for route calculation and vehicle positioning purposes to the navigation unit, which is integral to the Radio Receiver Module (RRM) (also known as the radio or the head unit). The antenna module receives time pulse information from the GPS satellites, then calculates and transmits altitude, latitude, longitude, number of satellites, satellite direction, satellite angle of elevation, direction, signal to noise ratio and accuracy information.

The hard wired circuits between components related to the navigation antenna module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the navigation antenna module or the electronic controls and communication between modules and other devices that provide some features of the navigation system. The most reliable, efficient and accurate means to diagnose the navigation antenna module or the electronic controls and communication related to navigation system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

SPARE TIRE

A compact (temporary) spare tire and wheel assembly is standard equipment on this vehicle.

Some vehicles are equipped with a Tire Inflator/Sealant tire repair kit as standard equipment in place of a spare tire. It is to be used to repair small punctures in the tire as necessary. For additional information, refer to the Owners Manual.

The compact spare tire is designed for emergency use only. The original tire should be repaired or replaced at the first opportunity, then reinstalled. Do not exceed speeds of 80 km/h (50 mph) when using the compact spare tire. Refer to the Owner's Manual for complete details.

STANDARD PROCEDURE - TOWING, VEHICLE

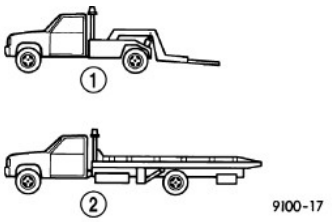
WARNINGS AND PRECAUTIONS

WARNING: **Do not allow towing attachment devices to contact the fuel tank or lines, fuel leakage can result. Do not lift or tow vehicle by front or rear bumper, or bumper energy absorber units. Do not venture under a lifted vehicle if not supported properly on safety stands. Do not allow passengers to ride in a towed vehicle. Use a safety chain that is independent from the towing attachment device. Failure to follow these instructions may result in personal injury or death.**

CAUTION: **Do not damage brake lines, exhaust system, shock absorbers, sway bars, or any other under vehicle components when attaching towing device to vehicle. Do not attach towing device to front or rear suspension components. Do not secure vehicle to towing device by the use of front or rear suspension or steering components. Remove or secure loose or protruding objects from a damaged vehicle before towing. Refer to state and local rules and regulations before towing a vehicle. Do not allow weight of towed vehicle to bear on lower fascia, air dams, or spoilers.**

RECOMMENDED TOWING EQUIPMENT

To avoid damage to bumper fascia and air dams use of a flat bed towing device or wheel lift is recommended. When using a wheel lift towing device, be sure the unlifted end of disabled vehicle has at least 100 mm (4 in.) ground clearance. If minimum ground clearance cannot be reached, use a towing dolly. If a flat bed device is used, the approach angle should not exceed 15 degrees.



Recommended Towing Equipment

1 - WHEEL LIFT

2 - FLAT BED

TOWING A DISABLED VEHICLE

WITHOUT THE IGNITION KEY

Front Wheel Drive (FWD)

Special care must be taken when the vehicle is towed with the ignition in the LOCK position. Flat bed towing is the preferred towing method. However, if a flat bed towing vehicle is not available, a wheel lift towing vehicle may be used. Furthermore, rear towing is not recommended with the front wheels on the ground, as transaxle damage can result. If rear towing is the only alternative, a front end dolly must be used. Proper towing equipment is necessary to prevent damage to the vehicle.

All Wheel Drive (AWD)

The vehicle must be transported on a flat bed truck.

Towing This Vehicle Behind Another Vehicle (Flat Towing With The Key In The Ignition And All Four Wheels On The Ground)

CAUTION:

- **If the vehicle being towed requires steering, the ignition switch must be in the ON position, not in the LOCK or ACC position.**
- **Do not attempt to tow this vehicle from the front with sling type towing equipment. Damage to the front fascia will result.**
- **Do not push or tow this vehicle with another vehicle as damage to the bumper fascia and transaxle may result.**

If you must use the accessories (wipers, defrosters, etc.) while being towed, the key must be in the ON position, not the ACC position. Make certain the transaxle remains in NEUTRAL.

Front Wheel Drive (FWD)

The vehicle may be towed under the following conditions: The shift lever must be in NEUTRAL, the distance to be traveled must not exceed 15 mi (25 km), and the towing speed must not exceed 25 mph (40 km/h). Exceeding these towing limits may cause a transaxle failure. If the transaxle is not operative, or if the vehicle is to be towed more than 15 mi (25 km), the vehicle must be transported either with a flat bed truck or with the front wheels off the ground.

All Wheel Drive (AWD)

The vehicle may be towed under the following conditions: The shift lever must be in NEUTRAL, the distance to be traveled must not exceed 15 mi (25 km), the towing speed must not exceed 25 mph (40 km/h), and both front and rear wheels must be on the ground. Exceeding these towing limits may cause a transaxle failure. If the transaxle is not operative, or if the vehicle is to be towed more than 15 mi (25 km), the vehicle must be transported on a flat bed truck.

Towing This Vehicle Behind Another Vehicle With A Tow Dolly

Front Wheel Drive (FWD)

Rear towing is not recommended with the front wheels on the ground, as transaxle damage can result. If rear towing is the only alternative, **a front end dolly must be used.** Proper towing equipment is necessary to prevent damage to the vehicle.

All Wheel Drive (AWD)

CAUTION: **The manufacturer does not recommend towing an All-Wheel Drive (AWD) on a tow dolly. Vehicle damage may occur.**

STANDARD PROCEDURE - ENHANCED SEATBELT REMINDER PROGRAMMING

The seatbelt indicator also includes a programmable enhanced seatbelt reminder or “BeltAlert®” feature that is enabled when the vehicle is shipped from the factory. This BeltAlert® feature provides extended, and modified visual seatbelt indicator, and audible chime warning responses to an unbuckled driver, or front passenger seat belt. For front passenger seats equipped with the BeltAlert® feature, the warning system may be triggered when an animal or heavy object is on the front passenger seat, or when the seat is folded flat (if equipped). The beltminder feature may be disabled or enabled by the customer using the programming sequence that follows, or by the dealer using a diagnostic scan tool. The following sequence of events must occur within sixty (60) seconds of the ignition switch being placed in the On position in order for the programming to be completed successfully.

1. With the ignition switch in any position except On or Start, buckle the driver side front seat belt.
2. Turn the ignition switch to the On position and wait for the seatbelt indicator reminder function to conclude (about six seconds).
3. Unbuckle and buckle the driver side front seat belt three or more times, ending with the belt buckled.
4. Turn the ignition switch to any position except On or Start to toggle the BeltAlert® feature from its current setting (from active to inactive, or from inactive to active). A single chime tone will provide an audible confirmation that the programming sequence has been successfully completed.

FRONT

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Position the front seat belt buckle (1) lower anchor to the bracket at the back of the inboard seat track.
2. Install and tighten the screw (3) that secures the lower anchor to the seat track bracket. Tighten the screw to 39 N·m (29 ft. lbs.).
3. Reinstall the front seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .
4. Reconnect the negative cable to the battery.

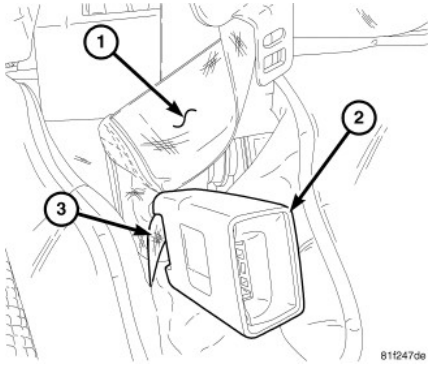
SECOND ROW - RIGHT

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. From the front of the second row right seat, engage the second row right buckle (2) through the elastic loop (3) of the right seat cushion trim cover and insert the buckle lower anchor between the right seat cushion and back trim covers.



2. Reach under the rear edge of the second row right seat cushion frame just to the right of the lower end of the inboard center seat back hinge bracket (1) to position the buckle lower anchor (3) and the center seat belt lower anchor (2) to the right seat frame.
3. Install and tighten the screw (4) that secures the buckle unit and the center seat belt lower anchor to the right seat frame. Tighten the screw to 39 N·m (29 ft. lbs.).
4. Restore the second row right seat to the fully rearward position.

THIRD ROW

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Reach between the two third row seat back hinge brackets on the rear floor panel (3) to position the third row seat belt buckle (1) anchor plate to the rear floor.
2. Install and tighten the screw (2) that secures the anchor plate to the rear floor panel. Tighten the screw to 90 N·m (66 ft. lbs.).
3. Reinstall the third row seat cushion and cover onto the rear floor panel (3) (Refer to 23 - Body/Seats/COVER, Seat Cushion - Installation) .

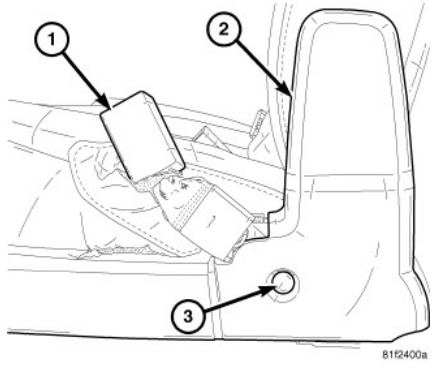
SECOND ROW - CENTER

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Move the second row right seat to the fully rearward position.
2. Move the second row left seat to the fully forward position.
3. Remove the plastic push-in fastener (3) that secures the outboard center seat back hinge bracket outboard trim (2) over the buckle (1) anchor to the left rear corner of the right seat frame.
4. Carefully pry the edges of the outboard center seat back hinge bracket outboard and inboard trim halves away from each other at their front and rear parting lines far enough to disengage the four integral latch features that secure the two halves of the trim to each other.



5. Carefully pry the outboard center seat back hinge bracket outboard trim away from the hinge bracket far enough to disengage the snap clip that secures the center of the trim to the bracket.
6. Remove the outboard trim from over the buckle anchor on the left rear corner of the right seat frame.
7. Remove the screw (2) that secures the buckle (1) lower anchor to the right seat frame.
8. Disengage the buckle from the elastic loop (3) of the right seat cushion trim cover and remove the buckle unit from the seat.

Failure to follow these instructions may result in possible serious or fatal injury.

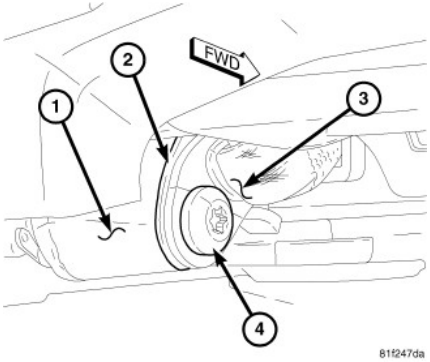
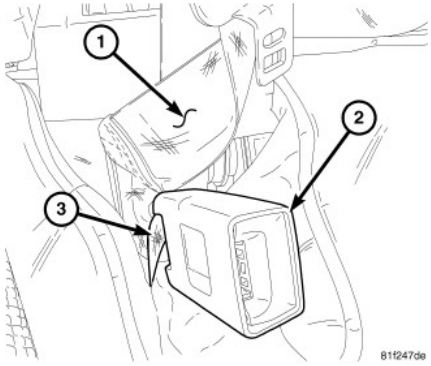
1. Move the second row right seat to the fully forward position.
2. Reach under the rear edge of the second row right seat cushion frame just to the right of the lower end of the inboard center seat back hinge bracket (1) to access the right buckle lower anchor (3) and the center seat belt lower anchor (2).
3. Remove the screw (4) that secures the right buckle lower anchor and the center seat belt lower anchor to the right seat cushion frame.



4. From the front of the second row right seat, disengage the buckle (2) from the elastic loop (3) of the right seat cushion trim cover and pull the buckle lower anchor out from between the right seat cushion and back trim covers.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The seat belt retractors used in all seating positions include an inertia-type, emergency locking mechanism as standard equipment. However, the retractor locking mechanism for all seating positions except the driver side front and the second row center are mechanically switchable from an emergency locking retractor to an automatic locking retractor. The primary function of this feature is to securely accommodate a child seat in these seating positions of the vehicle without the need for a self-cinching seat belt tip half latch plate unit or another supplemental device that would be required to prevent the seat belt webbing from unwinding freely from the retractor spool of an inertia-type emergency locking retractor mechanism.

The automatic locking mechanism is integral to the seat belt retractor unit and is concealed beneath a molded plastic cover located on the side of the retractor spool. The automatic locking mechanism cannot be adjusted or repaired and, if ineffective or damaged, the entire seat belt and retractor unit must be replaced.

FRONT

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

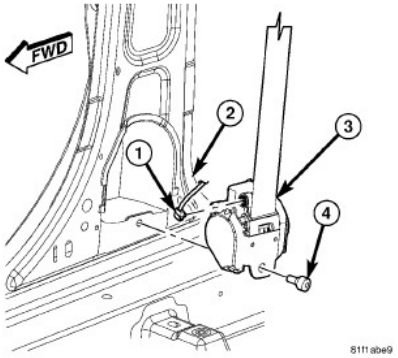
To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

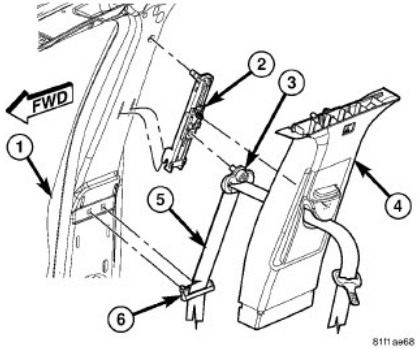
NOTE:

The following procedure is for replacement of an ineffective or damaged seat belt and retractor unit. The front retractor also includes a seat belt tensioner. If the front seat belt or retractor is ineffective or damaged, but the seat belt tensioner is not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the seat belt tensioner has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the front seat belt and retractor (3) to the inner B-pillar (2) as a unit.
2. On the driver side only, reconnect the body wire harness connector to the seat belt switch connector receptacle on the retractor.
3. Reconnect the body wire harness connector (1) to the seat belt tensioner initiator on the retractor.
4. Install and tighten the screw (4) that secures the lower retractor bracket to the inner B-pillar. Tighten the screw to 58 N·m (43 ft. lbs.).
5. Be certain to route the wiring for the seat belt tensioner behind the B-pillar flange to ensure it does not interfere with the seat belt webbing.
6. Position the web guide (6) to the B-pillar (1). Be certain the seat belt webbing (5) is not twisted between the retractor and the web guide.
7. Using hand pressure, press firmly and evenly on the web guide to snap it into place.
8. Position the seat belt turning loop onto the height adjuster (2) on the upper B-pillar. Be certain the seat belt webbing is not twisted between the web guide and the turning loop.
9. Install and tighten the screw (3) that secures the turning loop to the height adjuster. Tighten the screw to 37 N·m (27 ft. lbs.).

10. Reinstall the upper (4) and lower trim onto the B-pillar. (Refer to 23 - Body/Interior /PANEL, B-Pillar Trim - Installation) .



11. Position the front seat belt (1) lower anchor to the bracket on the outboard side of the front seat (2) cushion frame. Be certain the seat belt webbing is not twisted between the turning loop and the lower anchor.

12. Install and tighten the screw (4) that secures the lower anchor to the bracket on the outboard side of the front seat cushion frame. Tighten the screw to 51 N·m (38 ft. lbs.).

13. Align the seat belt anchor cover (3) to the opening near the rear of the outboard seat side shield. Using hand pressure, press firmly and evenly on the cover until it snaps into place.

14. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

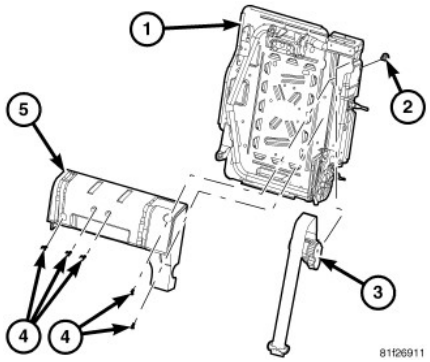
SECOND ROW - CENTER

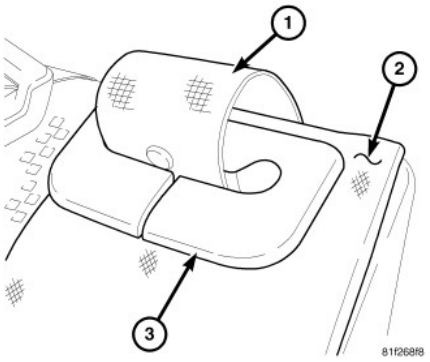
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.



1. Guide the seat belt webbing through the slot in the top of the right seat back frame (1) while positioning the center seat belt and retractor (3) to the frame as a unit. Be certain the seat belt webbing is not twisted between the retractor and the top of the seat.
2. Engage the T-tab of the retractor bracket with the keyed slot in the seat back frame.
3. From the back side of the seat back frame, install and tighten the screw (2) that secures the retractor to the frame. Tighten the screw to 39 N·m (29 ft. lbs.).
4. Position the molded plastic shield (5) onto the top of the seat back frame.
5. Install and tighten the screws (4) that secure the molded plastic shield to the top of the seat back frame. Pull the top of the seat back foam away from the seat back frame to access the lower screws securing the shield.
6. Reinstall the trim cover, back panel and head rest to the right seat back frame. (Refer to 23 - Body/Seats/SEAT BACK - Installation) .



7. Grasp the center seat belt webbing (1) between where it exits the top of the seat and the seat belt latch plate and slide it through the slot in the belt web guide bezel (3) to engage the belt through the bezel.
8. Position the guide bezel to the top of the right seat back (2) with the slot facing forward.
9. Using hand pressure, press the guide bezel down onto the top of the right seat back far enough to engage the three barrel clips that secure the bezel to the seat back frame.
10. From the front of the second row right seat, insert the center seat belt lower anchor between the right seat cushion and back trim covers. Be certain the seat belt webbing is not twisted between the top of the seat and the belt lower anchor.
11. Reach under the rear edge of the second row right seat cushion frame just to the right of the lower end of the inboard center seat back hinge bracket (1) to position the buckle lower anchor (3) and the center seat belt lower anchor (2) to the right seat frame.
12. Install and tighten the screw (4) that secures the buckle unit and the center seat belt lower anchor to the right seat frame. Tighten the screw to 39 N·m (29 ft. lbs.).

13. Reinstall the second row right seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .

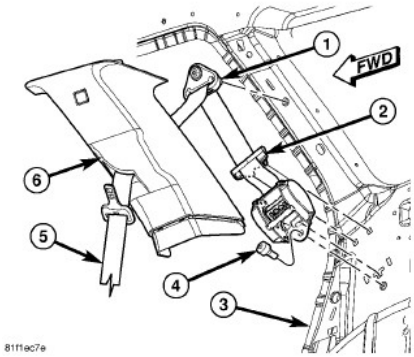
SECOND ROW - OUTBOARD

Labor Operations: Click to display a list of Labor Operations associated with this procedure

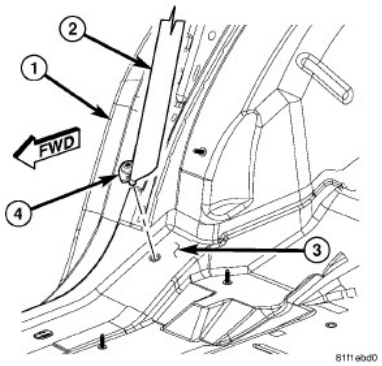
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Position the second row outboard seat belt and retractor (5) to the quarter inner panel just below the base of the upper C-pillar (3) as a unit.
2. Engage the tab on the retractor bracket into the keyed hole in the quarter inner panel.
3. Install and tighten the screw (4) that secures the retractor to the quarter inner panel. Tighten the screw to 58 N·m (43 ft. lbs.).
4. Position the web guide (2) to the quarter inner panel near the base of the C-pillar. Be certain the seat belt webbing is not twisted between the retractor and the web guide.



5. Using hand pressure, press firmly and evenly on the web guide to snap it into place.
6. Position the seat belt turning loop to the inside of the upper C-pillar. Be certain the seat belt webbing is not twisted between the web guide and the turning loop.
7. Install and tighten the screw (1) that secures the turning loop to the C-pillar. Tighten the screw to 43 N·m (32 ft. lbs.).
8. Reinstall the upper trim (2) onto the inside of the C-pillar (5). (Refer to 23 - Body/Interior/PANEL, C-Pillar Trim - Installation) .
9. Position the lower seat belt (2) anchor to the rear floor panel (3) near the base of the lower C-pillar (1). Be certain the seat belt webbing is not twisted between the turning loop and the lower anchor.
10. Install and tighten the screw (4) that secures the lower seat belt anchor to the floor. Tighten the screw to 58 N·m (43 ft. lbs.).
11. Reinstall the front of the quarter trim panel onto the lower C-pillar. (Refer to 23 - Body/Interior /PANEL, Quarter Trim - Installation) .

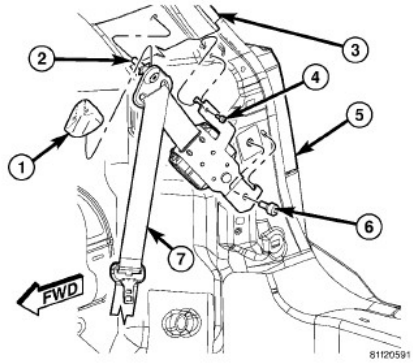


THIRD ROW SEAT BELT AND RETRACTOR

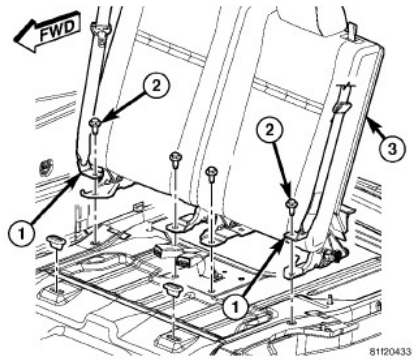
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.



1. Position the third row seat belt and retractor (7) to the inside of the D-pillar (5) as a unit.
2. Engage the tab of the upper retractor bracket into the keyed hole in the D-pillar.
3. Install and tighten the screw (6) that secures the lower retractor bracket to the inside of the D-pillar. Tighten the screw to 58 N·m (43 ft. lbs.).
4. Install and tighten the screw (4) that secures the upper retractor bracket to the inside of the D-pillar. Tighten the screw to 10 N·m (7 ft. lbs.).
5. Reinstall the rear of the quarter trim panel to the lower D-pillar (Refer to 23 - Body/Interior /PANEL, Quarter Trim - Installation) .
6. Reinstall the trim (3) onto the inside of the upper D-pillar (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Installation) .
7. Position the seat belt turning loop to the inside of the upper D-pillar. Be certain the seat belt webbing (5) is not twisted between the retractor and the turning loop.
8. Install and tighten the screw (2) that secures the turning loop to the bracket on the inside of the upper D-pillar. Tighten the screw to 43 N·m (32 ft. lbs.).
9. Snap the trim cover (1) over the seat belt turning loop on the inside of the upper D-pillar.



10. Position the seat belt lower anchor (1) to the third row seat back (3) outboard bracket on the rear floor panel. Be certain the seat belt webbing is not twisted between the turning loop and the lower anchor.
11. Install and tighten the screw (2) that secures the lower anchor and the third row seat back outboard bracket to the rear floor panel. Tighten the screw to 90 N·m (66 ft. lbs.).
12. Reinstall the third row seat cushion and cover to the rear floor panel (Refer to 23 - Body/Seats/COVER, Seat Cushion - Installation) .

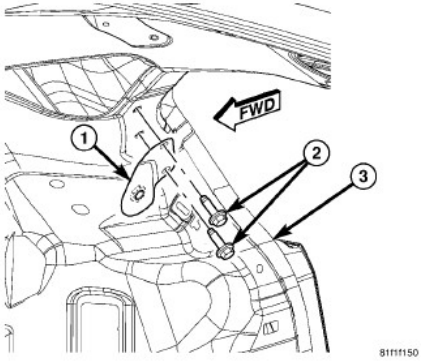
THIRD ROW TURNING LOOP BRACKET

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Position the third row turning loop bracket (1) to the inside of the upper D-pillar (3).
2. Install and tighten the two screws (2) that secure the turning loop bracket to the D-pillar. Tighten the screws to 22 N·m (16 ft. lbs.).



3. Reinstall the trim (3) onto the inside of the upper D-pillar. (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Installation) .
4. Position the seat belt turning loop to the inside of the upper D-pillar. Be certain the seat belt webbing (5) is not twisted between the retractor and the turning loop as well as between the turning loop and the lower anchor.
5. Install and tighten the screw (2) that secures the turning loop to the bracket on the inside of the upper D-pillar. Tighten the screw to 43 N·m (32 ft. lbs.).
6. Snap the trim cover (1) over the seat belt turning loop on the inside of the upper D-pillar.

OPERATION

The locked mode of the retractor is engaged and the automatic locking retractor is switched from operating as a standard inertia-type emergency locking retractor by first buckling the combination lap and shoulder belt buckle. Then grasp the shoulder belt and pull all of the webbing out of the retractor. Once all of the belt webbing is extracted from the spool, the retractor will automatically become engaged in the pre-locked automatic locking mode and will make an audible clicking or ratchet-like sound as the shoulder belt is allowed to retract to confirm that the automatic locking mode is now engaged. Once the automatic locking mode is engaged, the retractor will remain locked and the belt will remain tight around whatever it is restraining.

The retractor is returned to standard emergency locking (inertia) mode by unbuckling the combination lap and shoulder belt buckle and allowing the belt webbing to be almost fully retracted onto the retractor spool. The emergency locking mode is confirmed by the absence of the audible clicking or ratchet-like sound as the belt webbing retracts. This mode will allow the belt to unwind from and wind onto the retractor spool freely unless and until a predetermined inertia load is sensed, or until the retractor is again switched to the automatic locking mode.

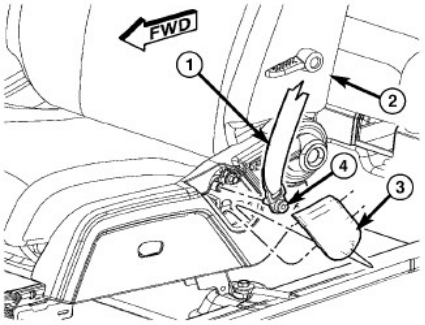
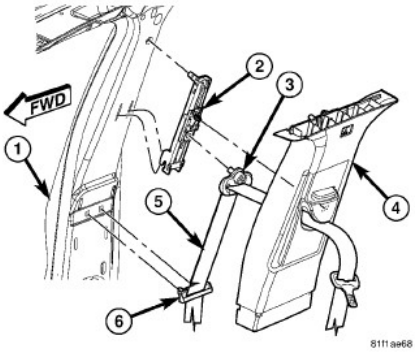
NOTE: The following procedure is for replacement of an ineffective or damaged seat belt and retractor unit. The front retractor also includes a seat belt tensioner. If the front seat belt or retractor is ineffective or damaged, but the seat belt tensioner is not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the seat belt tensioner has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



8111a4e7

1. Adjust the front seat to its most forward position for easiest access to the front seat belt lower anchor and the B-pillar trim.
2. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
3. Using a trim stick or another suitable wide flat-bladed tool, gently pry the seat belt anchor cover (3) to remove it from the rear of the outboard front seat (2) side shield.
4. Remove the screw (4) that secures the front seat belt (1) lower anchor to the bracket on the outboard side of the front seat cushion frame.
5. Remove the lower and upper trim (4) from the B-pillar (1). (Refer to 23 - Body/Interior /PANEL, B-Pillar Trim - Removal) .
6. Remove the screw (3) that secures the seat belt (5) turning loop to the height adjuster (2) on the upper B-pillar.
7. Using a trim stick or another suitable wide flat-bladed tool, gently pry the seat belt web guide (6) to unsnap it from the B-pillar.



8111ae68

8. Disconnect the body wire harness connector (1) from the seat belt tensioner initiator on the retractor (3).
9. On the driver side only, disconnect the second body wire harness connector from the seat belt switch connector receptacle on the retractor.
10. Remove the screw (4) that secures the lower retractor bracket to the inner B-pillar (2).
11. Remove the front seat belt and retractor from the B-pillar as a unit.

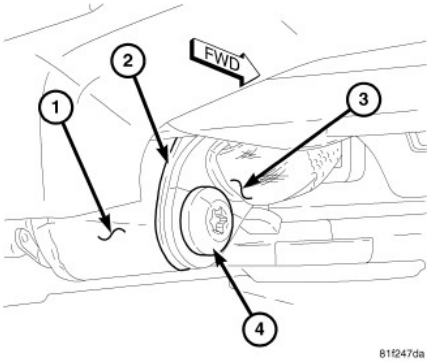
SECOND ROW - CENTER

Labor Operations: Click to display a list of Labor Operations associated with this procedure

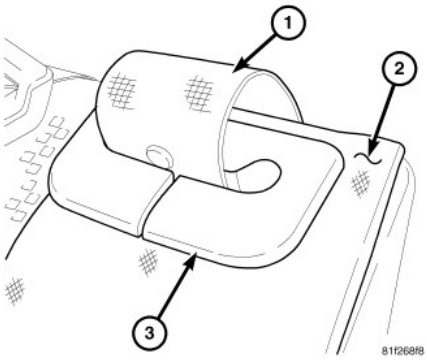
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

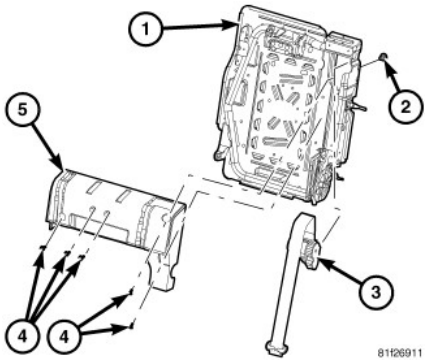
1. Remove the second row right seat from the vehicle. (Refer to 23 - Body/Seats/SEAT - Removal) .
2. Reach under the rear edge of the second row right seat cushion frame just to the right of the lower end of the inboard center seat back hinge bracket (1) to access the right buckle lower anchor (3) and the center seat belt lower anchor (2).
3. Remove the screw (4) that secures the right buckle lower anchor and the center seat belt lower anchor to the right seat cushion frame.
4. From the front of the second row right seat, pull the center seat belt lower anchor out from between the right seat cushion and back trim covers.



5. Using a trim stick or another suitable wide flat-bladed tool, carefully pry the belt web guide bezel (3) upward from the top of the right seat back (2) far enough to disengage the three barrel clips that secure the bezel to the seat back frame.
6. Slide the center seat belt webbing (1) through the slot in the guide bezel to disengage the belt from the bezel.



7. Remove the head rest, back panel and trim cover from the right seat back frame (1). It is not necessary to remove the seat back frame from the seat cushion frame. (Refer to 23 - Body/Seats/SEAT BACK - Removal) .
8. Remove the screws (4) that secure the molded plastic shield (5) to the top of the seat back frame. Pull the top of the seat back foam away from the seat back frame to access the lower screws securing the shield.
9. Remove the molded plastic shield from the top of the seat back frame.
10. From the back side of the seat back frame, remove the screw (2) that secures the retractor (3) to the frame.



11. Lift the retractor upward far enough to disengage the T-tab of the retractor bracket from the keyed slot in the seat back frame.

12. Guide the seat belt webbing through the slot in the top of the seat back frame while removing the seat belt and retractor from the seat as a unit.

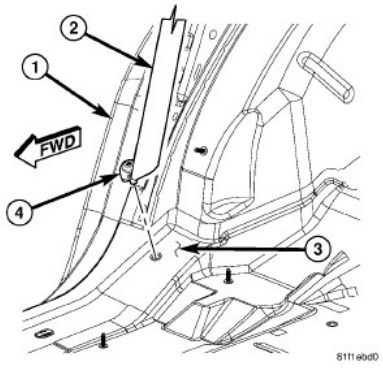
SECOND ROW - OUTBOARD

Labor Operations: Click to display a list of Labor Operations associated with this procedure

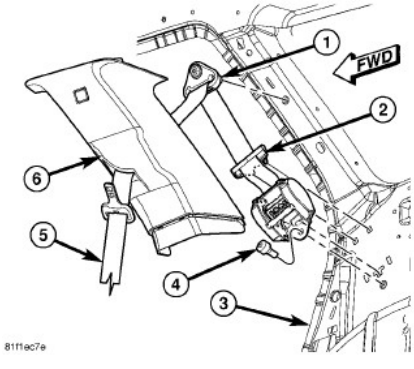
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Loosen the front of the quarter trim panel from the lower C-pillar (1) enough to access the second row outboard seat belt and retractor. (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Removal) .
2. Remove the screw (4) that secures the second row outboard seat belt (2) lower anchor to the rear floor panel (3) near the base of the C-pillar.



3. Remove the upper trim (6) from the inside of the C-pillar (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Removal) .
4. Remove the screw (1) that secures the seat belt turning loop to the inside of the upper C-pillar (3).
5. Remove the seat belt turning loop from the C-pillar.
6. Using a trim stick or another suitable wide flat-bladed tool, gently pry the seat belt web guide (2) to unsnap it from the quarter inner panel near the base of the C-pillar.



7. Remove the screw (4) that secures the retractor (5) bracket to the quarter inner panel.
8. Lift the retractor upward far enough to disengage the retractor tab from the keyed hole in the quarter inner panel.
9. Remove the second row outboard seat belt and retractor from the vehicle as a unit.

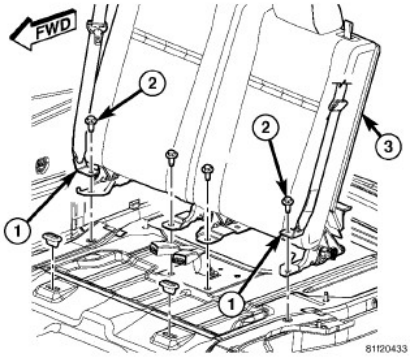
THIRD ROW SEAT BELT AND RETRACTOR

Labor Operations: Click to display a list of Labor Operations associated with this procedure

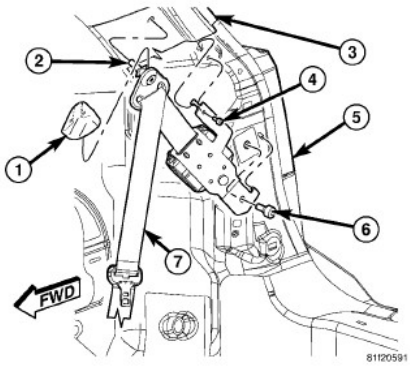
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Remove the third row seat cushion and cover from the rear floor panel (Refer to 23 - Body/Seats /COVER, Seat Cushion - Removal) .
2. Remove the screw (2) that secures the third row seat belt lower anchor (1) and the third row seat back (3) outboard bracket to the rear floor panel.
3. Remove the lower anchor from the third row seat back outboard bracket.



4. Pry between the back of the third row seat belt turning loop on the inside of the upper D-pillar trim (3) and the back of the trim cover (1) to unsnap and remove it for access to the turning loop screw (2).
5. Remove the screw (2) that secures the seat belt turning loop to the bracket on the inside of the upper D-pillar.
6. Remove the turning loop from the D-pillar.
7. Remove the trim from the inside of the upper D-pillar (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Removal) .



8. Loosen the rear of the quarter trim panel from the lower D-pillar enough to access the third row outboard seat belt and retractor (7) (Refer to 23 - Body/Interior /PANEL, Quarter Trim - Removal) .
9. Remove the screw (4) that secures the upper retractor bracket to the inside of the D-pillar.
10. Remove the screw (6) that secures the lower retractor bracket to the inside of the D-pillar.
11. Lift the retractor upward far enough to disengage the tab of the upper retractor bracket from the keyed hole in the D-pillar.
12. Remove the third row seat belt and retractor from the vehicle as a unit.

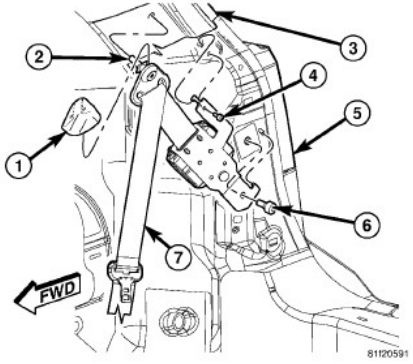
THIRD ROW TURNING LOOP BRACKET

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Unsnap and remove the trim cover (1) from the third row seat belt turning loop on the inside of the upper D-pillar trim (3) to access the turning loop screw (2).
2. Remove the screw (2) that secures the seat belt turning loop to the bracket on the inside of the upper D-pillar.
3. Remove the turning loop from the D-pillar.
4. Remove the trim from the inside of the upper D-pillar. (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Removal) .



5. Remove the two screws (2) that secure the seat belt turning loop bracket (1) to the inside of the upper D-pillar (3).
6. Remove the turning loop bracket from the D-pillar.

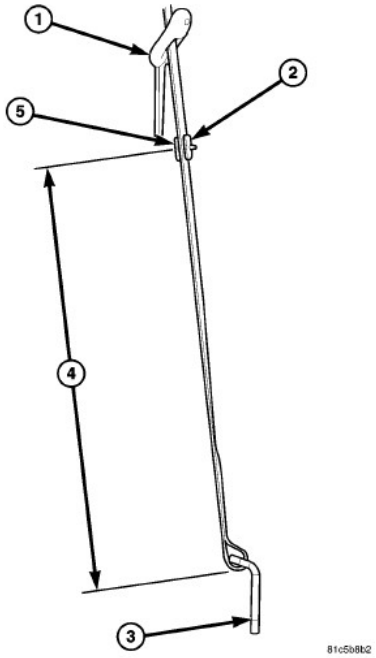
STANDARD PROCEDURE - WEB STOP BUTTON REPLACEMENT

WARNING: **To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.**

The webbing of the second row center seat belt tip half for this vehicle is equipped with a molded plastic web stop button, which holds the latch plate of the seat belt tip half in a readily accessible stored position and prevents it from falling to the lower belt anchor while the belt is not in use. If this button becomes damaged or separated from the belt webbing, it may be successfully replaced using the following procedure without the need for removing or replacing the entire seat belt assembly.

The web stop button replacement kit includes two molded plastic replacement button halves: a male button half with a pointed spike in its center, and a female button half with a hole in its center. The button halves are not available separately. In addition to the button replacement kit, a pair of wheel weight pliers (such as KD Tools® #3358, Snap-on® #WWPR13A or equivalent) and a gel-type super adhesive glue (such as Mopar® Bond-All Gel #04467709 or equivalent) are required.



NOTE: Avoid using heavy-duty, truck-style wheel weight pliers as the jaws may not close far enough to successfully complete web stop button replacement.

1. Carefully inspect the seat belt webbing to identify the hole or a witness mark where the original web stop button halves (2 and 5) were installed. If no distinct evidence of the prior button location is found, go to Step 2. If the original button location is clearly evident, go to Step 3.
2. Find the appropriate dimension in the Web Stop Button Location table. Measure and mark that distance (4) in the center of the belt webbing from the point where the webbing is secured to the seat belt lower anchor plate (3).

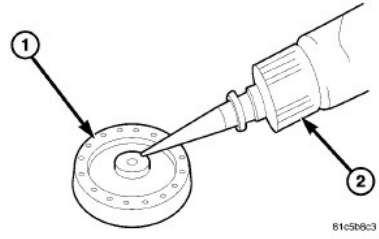
WEB STOP BUTTON LOCATION

SEATING POSITION	DIMENSION
SECOND ROW CENTER	260 plus or minus 5 millimeters (10.24 plus or minus 0.20 inches)

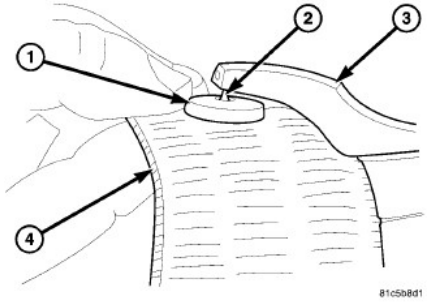
CAUTION: **Be certain that the seat belt latch plate (1) is located and secured above the web stop button location mark before installing the replacement button.**

3. Working from the side of the seat belt webbing that faces the interior of the vehicle, pierce the webbing with the spike in the center of the male button half. The male button head should face the interior of the vehicle.
4. Apply a small dot of gel-type super adhesive glue (2) around the center hole on the back side of the female button half (1).

5. Press the female button half over the spike of the male button half that protrudes through the side of the belt webbing that faces away from the interior of the vehicle.



6. Use the flat anvil-like jaw (3) of the wheel weight pliers to flatten the sharp spike (2) of the male button half that protrudes through the female button half (1) on the back side of the belt webbing (4).



7. Carefully use the curved jaw (3) of the wheel weight pliers to compress and form the flattened spike of the male button half (2) on the back side of the seat belt webbing (1) until it is concave and entirely below the outer convex surface of the female button half.

8. Check to be certain that the web stop button is secure.

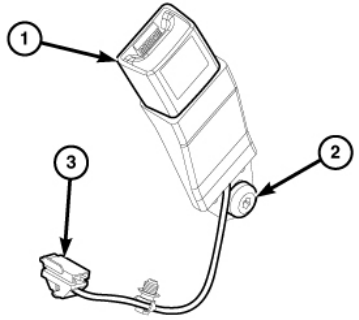
Fuel Delivery: | **Fuel:**

DESCRIPTION

The driver and passenger side front seat belt switches for this vehicle are actually Hall Effect-type sensors. These sensors consist of a fixed-position, Hall Effect Integrated Circuit (IC) chip and a small permanent magnet that is integral to each front seat belt buckle (1). The front seat belt buckles are located on a molded plastic scabbard and secured by a screw (2) to the inboard side of each front seat cushion frame so that the buckles travel with the seat.

The front seat belt switches are connected to the vehicle electrical system through a two-lead pigtail wire and connector (3) on the front seat belt buckle-half, which is connected to a wire harness connector and take out of the seat wire harness. A one kilohm diagnostic resistor is connected in parallel with the IC where the two pigtail wire leads connect to the IC pins.

The seat belt switches cannot be adjusted or repaired and, if ineffective or damaged, the entire front seat belt buckle-half unit must be replaced.



3085925

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The front seat belt switches are designed to control a hard wired sense input to the Occupant Restraint Controller (ORC). A spring-loaded slide with a small window-like opening is integral to the buckle latch mechanism. When a seat belt tip-half is inserted and latched into the seat belt buckle, the slide is pushed downward and the window of the slide exposes the Hall Effect Integrated Circuit (IC) chip within the buckle. The field of the permanent magnet induces a current within the chip. The chip provides this induced current as an output to the ORC. When the seat belt is unbuckled, the spring-loaded slide moves upward and shields the IC from the field of the permanent magnet, causing the output current from the seat belt switch to be reduced.

The seat belt switches receive a supply of current from the ORC, and the ORC senses the status of the front seat belt switches through its connection to the seat wire harness. The ORC provides electronic **seat belt switch status** messages to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) over the Controller Area Network (CAN) data bus. The IC uses these messages as an additional logic input for control of the seat belt indicator. The ORC monitors the condition of the seat belt switch circuits and will store a Diagnostic Trouble Code (DTC) for any fault that is detected.

The hard wired circuits between the seat belt switches and the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the switches or the electronic controls and communication between other modules and devices that provide some features of the seat belt reminder system. The most reliable, efficient and accurate means to diagnose the seat belt switches or the electronic controls and communication related to seat belt switch operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

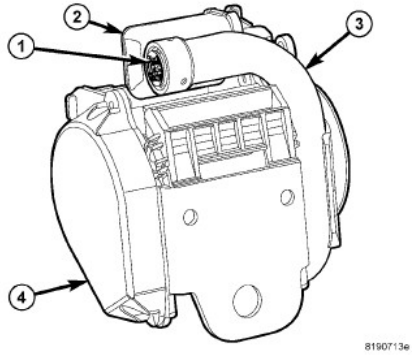
DESCRIPTION

In vehicles manufactured for domestic markets, the passenger side front seat belt incorporates dual tensioners: one integral to the retractor, and one integral to the buckle. In vehicles manufactured for export markets, the passenger side front seat belt uses a single retractor tensioner. The driver side retractor for all markets incorporates a single retractor tensioner.

RETRACTOR TENSIONER

Seat belt retractor tensioners supplement the dual front airbag system for all versions of this vehicle. These tensioners are integral to the front seat belt and retractor units (4), which are secured to the inner B-pillar on the right and left sides of the vehicle. The retractor is concealed beneath the molded plastic inner B-pillar trim. The seat belt tensioner consists primarily of a sprocket/pinion, a steel tube (3), a cast metal housing, numerous steel balls, a stamped metal ball trap (2), a torsion bar and a small pyrotechnically activated gas generator with a connector receptacle (1).

All of these components are located on one side of the retractor spool on the outside of the retractor housing except for the torsion bar, which serves as the spindle upon which the retractor spool rides. The seat belt tensioners are controlled by the Occupant Restraint Controller (ORC) and are connected to the vehicle electrical system through a dedicated take outs of the body wire harness by keyed and latching yellow molded plastic connector insulator to ensure a secure connection.



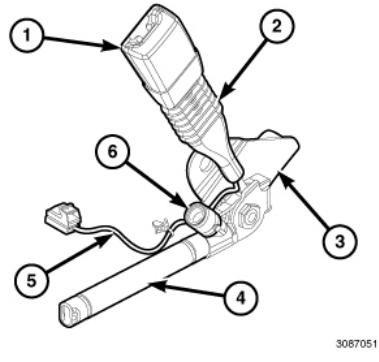
The retractor tensioners cannot be repaired and, if ineffective or damaged, the entire front seat belt and retractor unit must be replaced. If the front airbags have been deployed, the seat belt tensioners have also been deployed. The seat belt tensioners are not intended for reuse and must be replaced following any front airbag deployment. A growling or grinding sound while attempting to operate the seat belt retractor is a sure indication that the seat belt tensioner has been deployed and requires replacement. (Refer to 10 - Restraints/RETRACTOR, Seat Belt - Removal) .

BUCKLE TENSIONER

A passenger side seat belt buckle tensioner supplements the dual front airbags for domestic market versions of this vehicle. This tensioner is integral to the right front seat belt buckle unit, which is secured by a large screw to the outside of the inboard seat cushion frame of the front seat. The buckle tensioner consists primarily of a buckle (1), a molded plastic scabbard (2), a cable and piston, a cable guide and bracket (3), a metal cylinder tube (4) and a small pyrotechnically activated gas generator (6).

The buckle tensioner is controlled by the Occupant Restraint Controller (ORC) and is connected to the vehicle electrical system through a dedicated take out of the seat wire harness by a keyed and latching yellow molded plastic connector insulator to ensure a secure connection. The buckle tensioner has a single pigtail harness (5) for the integral seat belt switch.

The buckle tensioner cannot be repaired and, if ineffective or damaged, the entire front seat belt buckle unit must be replaced. If the front airbags have been deployed, the buckle tensioners have also been deployed. The buckle tensioners are not intended for reuse and must be replaced following any front airbag deployment. (Refer to 10 - Restraints/BUCKLE, Seat Belt - Removal) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The seat belt tensioners are deployed in conjunction with the dual front airbags by a signal generated by the Occupant Restraint Controller (ORC) through the driver or passenger seat belt tensioner line 1 and line 2 (or squib) circuits. When the ORC sends the proper electrical signal to the tensioners, the electrical energy generates enough heat to initiate a small pyrotechnic gas generator.

On the retractor tensioner, the gas generator is installed in one end of a steel tube that contains numerous steel balls. As the gas expands, it pushes the steel balls through the tube into a cast metal housing, where a ball guide directs the balls into engagement with the teeth of a sprocket that is geared to one end of the retractor spool. As the balls drive past the sprocket, the sprocket turns and drives the seat belt retractor spool causing the slack to be removed from the front seat belts. The ball trap captures the balls as they leave the sprocket and are expelled from the housing.

On the buckle tensioner, the gas generator is installed in one end of the tubular metal piston housing, which contains a piston secured to one end of a cable. The cable is routed around an integral guide to the buckle, which is secured to the opposite end of the cable. As the gas expands, it pushes the piston and the cable through the tube and pulls the buckle downward, causing the slack to be removed from the passenger side front seat belt.

Removing excess slack from the front seat belts not only keeps the occupants properly positioned for an airbag deployment following a frontal impact of the vehicle, but also helps to reduce injuries that the occupants of the front seats might experience in these situations as a result of harmful contact with the steering wheel, steering column, instrument panel or windshield. The seat belt retractor also has a torsion bar mechanism that is designed to deform in order to control the loading being applied to the occupants by the seat belts during a frontal impact, further reducing the potential for occupant injuries.

The ORC monitors the condition of the seat belt tensioners through circuit resistance, and will illuminate the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the seat belt tensioner gas generator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

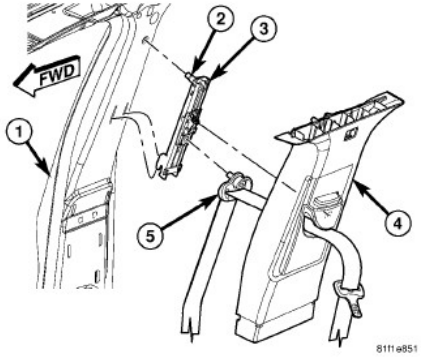
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.



1. Position the seat belt turning loop height adjuster (3) to the upper inner B-pillar (1).
2. Engage the tabs at the bottom of the height adjuster into the slots in the B-pillar.
3. Install and tighten the screw (2) that secures the height adjuster to the B-pillar. Tighten the screw to 58 N·m (43 ft. lbs.).
4. Position the seat belt turning loop onto the height adjuster on the upper B-pillar. Be certain the seat belt webbing is not twisted between the turning loop and the web guide or between the turning loop and the lower anchor.
5. Install and tighten the screw (2) that secures the turning loop to the height adjuster. Tighten the screw to 37 N·m (27 ft. lbs.).
6. Reinstall the upper trim (4) onto the inside of the B-pillar. (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Installation) .

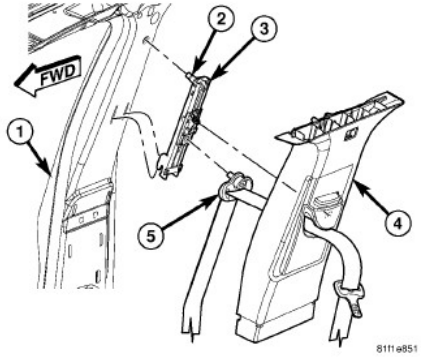
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.**



1. Adjust the front seat to its most forward position for easiest access to the B-pillar trim.
2. Remove the upper trim (4) from the B-pillar (1). (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Removal) .
3. Remove the screw that secures the seat belt turning loop (5) to the height adjuster (3) on the upper B-pillar.
4. Remove the seat belt turning loop from the height adjuster.
5. Remove the screw (2) that secures the top of the height adjuster to the B-pillar.
6. Disengage the tabs at the bottom of the height adjuster from the slots in the B-pillar.
7. Remove the adjuster from the B-pillar.

ASSEMBLY

Labor Operations: Click to display a list of Labor Operations associated with this procedure

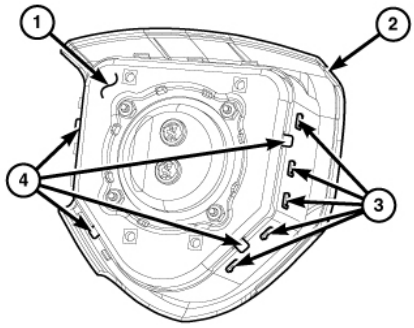
WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, service of this unit should be performed only by Chrysler-trained and authorized dealer service technicians. Failure to take the proper precautions or to follow the proper procedures could result in accidental, incomplete, or improper airbag deployment and possible occupant injuries.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the Driver AirBag (DAB), or becoming entrapped between the DAB cushion and the DAB trim cover. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

WARNING: **To avoid serious or fatal injury, the Driver AirBag (DAB) trim cover must never be painted. Replacement trim covers are serviced in the original colors. Paint may change the way in which the material of the trim cover responds to an airbag deployment. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

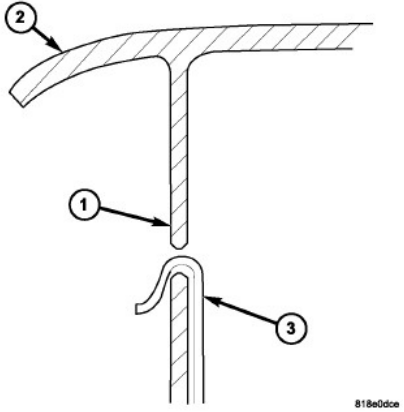
NOTE: The following procedures can be used to replace the Driver AirBag (DAB) trim cover for service of cosmetic damage issues. If the DAB is ineffective or deployed, the entire DAB and trim cover must be replaced as a unit.



2939410

1. Place the Driver AirBag (DAB) trim cover (2) on a suitable clean and dry work surface with the receptacle facing up. Be certain to take the proper precautions to prevent the trim cover from receiving cosmetic damage during the following procedures.
2. Position the DAB housing (1), inflator, and cushion as a unit over the trim cover receptacle.
3. Using hand pressure, push the airbag housing firmly and evenly down into the trim cover receptacle far enough that the hooks (3) of the housing are aligned with the windows in the vertical walls of the receptacle.
4. Work around the perimeter of the unit engaging each of the thirteen hooks on the DAB housing through the thirteen windows in the walls of the trim cover receptacle.
5. After the DAB has been assembled, try pulling the trim cover and the airbag housing away from each other. This action will fully seat the edges of the windows into the cradles of the hooks and the vertical walls of the receptacle beneath the locating tabs (4) of the housing.
6. Before reinstalling the airbag onto the steering wheel, check that the blocking tab (1) in each of the trim cover (2) windows is oriented over the airbag housing hook (3) as shown.

7. Reinstall the DAB onto the steering wheel. (Refer to 10 - Restraints/AIR BAG, Driver - Installation) .

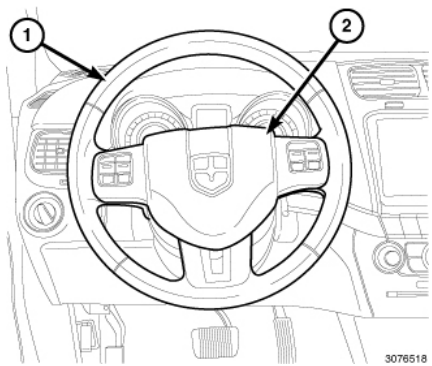


2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The injection molded, thermoplastic Driver AirBag (DAB) protective trim cover (2) is the most visible part of the DAB. The DAB is located in the center of the steering wheel (1), where it is secured with screws to the floating horn switch within the hub cavity of the three-spoke steering wheel. An injection molded, bright Dodge emblem is applied to the center of the trim cover.



Concealed beneath the DAB trim cover (1) are the folded airbag cushion, the airbag housing (2), the airbag inflator (3) and the retainers (5) that secure the inflator to the housing. The airbag cushion, housing and inflator are secured within an integral receptacle molded into the back of the trim cover. The vertical walls of this receptacle have numerous integral window features that are engaged by numerous hook features that are bent outward around the perimeter of the DAB housing. The DAB housing also has four well nuts (4) which are used to secure the floating horn switch to the back of the housing.

The DAB used in this vehicle is a multistage-type that complies with revised federal airbag standards to deploy with less force than those used in some prior vehicles. A radial deploying 67.3 centimeter (26.5 inch) diameter fabric airbag cushion with internal tethers is used. The airbag inflator is a dual-initiator, non-azide, pyrotechnic-type unit and is secured to the stamped metal airbag housing using four flanged hex nuts. Two keyed and color-coded connector receptacles on the DAB inflator connect the two inflator initiators to the vehicle electrical system through two jacketed, two-wire pigtail harnesses from the clockspring.

The DAB cannot be repaired, and must be replaced if deployed, ineffective or in any way damaged. The DAB trim cover and the floating horn switch are available for individual service replacement.

INSTALLATION

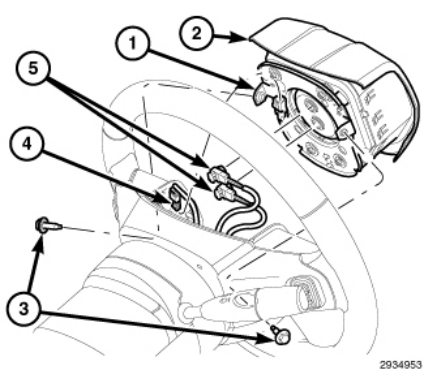
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the Driver AirBag (DAB), or becoming entrapped between the DAB cushion and the DAB trim cover. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

WARNING: **To avoid serious or fatal injury, the driver airbag trim cover must never be painted. Replacement airbags are serviced with trim covers in the original colors. Paint may change the way in which the material of the trim cover responds to an airbag deployment. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Driver AirBag (DAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the DAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the Driver AirBag (DAB) (2) and floating horn switch (1) unit close enough to the steering wheel to reconnect the electrical connections to the back of the airbag housing.
2. Reconnect the steering wheel wire harness connector (4) to the floating horn switch connector on the back of the switch.
3. Reconnect the wire connectors (5) to the airbag inflator connector receptacles by pressing straight in on the connector insulator. Be certain to engage each keyed and color-coded connector to the matching connector receptacle. You can be certain that each connector is fully engaged in its receptacle by listening carefully for a distinct, audible click as the connector latches snap into place.
4. Be certain to fully engage the plastic push-in retainer of the clockspring pigtail wires into the locator hole at the 12 o'clock position on the back of the floating horn switch.
5. Carefully position the DAB and floating horn switch unit into the steering wheel hub while tugging lightly upward on the clockspring pigtail wires for the airbag and tucking the wires into the upper hub cavity of the steering wheel. Be certain that none of the steering wheel wiring is pinched between the airbag housing or the horn switch and the steering wheel armature or, on vehicles equipped with a diesel engine, the steering wheel damper weight.
6. Working through the access holes in each side of the steering wheel rear trim cover, install and tighten the two screws (3) that secure the floating horn switch and DAB unit to the steering wheel armature. Tighten the screws to 13 N·m (10 ft. lbs.).
7. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

OPERATION

The multistage Driver AirBag (DAB) is deployed by electrical signals generated by the Occupant Restraint Controller (ORC) through the DAB squib 1 and squib 2 circuits to the two initiators in the airbag inflator. By using two initiators, the airbag can be deployed at multiple levels of force. The force level is controlled by the ORC to suit the monitored impact conditions by providing one of several delay intervals between the electrical signals provided to the two initiators. The longer the delay between these signals, the less forcefully the airbag will deploy.

When the ORC sends the proper electrical signals to each initiator, the electrical energy generates enough heat to initiate a small pyrotechnic charge which, in turn ignites chemical pellets within the inflator. Once ignited, these chemical pellets burn rapidly and produce a large quantity of inert gas. The inflator is sealed to the back of the airbag housing and a diffuser in the inflator directs all of the inert gas into the airbag cushion, causing the cushion to inflate. As the cushion inflates, the DAB trim cover will split at predetermined breakout lines, then fold back out of the way. Following an airbag deployment, the airbag cushion quickly deflates by venting the inert gas towards the instrument panel through vent holes within the fabric used to construct the back (steering wheel side) panel of the airbag cushion.

Some of the chemicals used to create the inert gas may be considered hazardous while in their solid state before they are burned, but they are securely sealed within the airbag inflator. Typically, both initiators are used and all potentially hazardous chemicals are burned during an airbag deployment event. However, it is possible for only one initiator to be used during a deployment due to an airbag system fault; therefore, it is necessary to always confirm that both initiators have been used in order to avoid the improper disposal of potentially live pyrotechnic or hazardous materials. (Refer to 10 - Restraints - Standard Procedure) .

The inert gas that is produced when the chemicals are burned is harmless. However, a small amount of residue from the burned chemicals may cause some temporary discomfort if it contacts the skin, eyes, or breathing passages. If skin or eye irritation is noted, rinse the affected area with plenty of cool, clean water. If breathing passages are irritated, move to another area where there is plenty of clean, fresh air to breath. If the irritation is not alleviated by these actions, contact a physician.

The ORC monitors the condition of the DAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the DAB initiator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

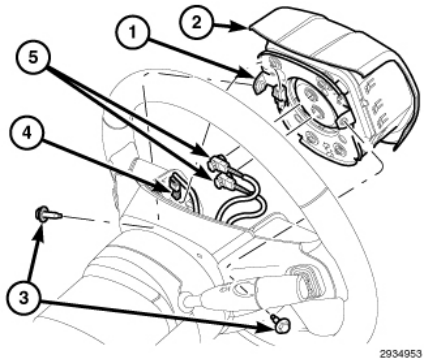
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag cushion and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

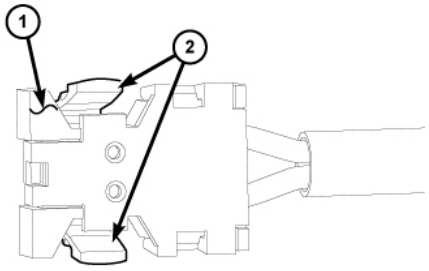
NOTE: The following procedure is for replacement of an ineffective or damaged Driver AirBag (DAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the DAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



2934953

1. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Working through the access holes in each side of the steering wheel rear trim cover, remove the two screws (3) that secure the floating horn switch (1) and Driver AirBag (DAB) (2) unit to the steering wheel armature.
3. Pull the DAB away from the steering wheel far enough to access and disengage the plastic push-in retainer of the clockspring pigtail wire harness from the locator hole at the 12 o'clock position on the back of the floating horn switch.
4. Pull the DAB and floating horn switch unit away from the steering wheel far enough to access the electrical connections (3 and 4) at the back of the airbag housing and switch unit.
5. Disconnect the steering wheel wire harness connector (4) from the floating horn switch connector on the back of the switch.

CAUTION: **Do not pull on the clockspring pigtail wires or pry on the connector insulators to disengage them from the Driver AirBag (DAB) inflator initiator connector receptacles. Improper removal of these pigtail wires and their connector insulators can result in damage to the airbag circuits or the connector insulators.**



2128307

6. The clockspring DAB pigtail wire connector insulators (1) are secured by integral latches (2) to the airbag inflator connector receptacles, which are located on the back of the DAB housing. Pinch both latches firmly, then pull the insulators straight out from the airbag inflator to disconnect them from the connector receptacles.
7. Remove the DAB from the steering wheel.

8. If the DAB has been deployed, the clockspring and the steering column must be replaced.

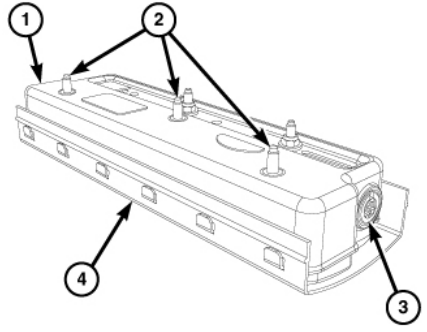
DESCRIPTION

A Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB) is used on vehicles manufactured for domestic markets. These airbags are passive, inflatable, Supplemental Restraint System (SRS) components. Vehicles with this equipment may be readily identified by the **SRS - AIRBAG** logo located on the upper outboard corner of the instrument panel steering column opening cover.

The KAB is concealed behind the steering column opening cover below the steering column on the driver side lower instrument panel. Located behind the steering column opening cover, the stamped metal airbag housing (1) is secured by three studs (2) with nuts to the stamped metal instrument panel lower reinforcement and mounting plate. A molded plastic protective cover (4) is secured over the folded airbag cushion by numerous hook formations stamped into the airbag housing that are engaged through window openings in the outer perimeter of the cover.

The airbag housing contains the airbag inflator and a heat shield. The airbag inflator is a single-initiator, non-azide hybrid-type unit that is secured to the housing by two studs with nuts and sealed within the airbag housing. The airbag is connected to the vehicle electrical system through a dedicated take out and connector insulator of the instrument panel wire harness that connects directly to the inflator initiator (3).



The KAB cannot be repaired, and must be replaced if deployed, ineffective or in any way damaged. If the airbag is deployed, the KAB and the steering column opening cover must be replaced.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the Inflatable Knee Blocker (IKB) airbag, or becoming entrapped between the IKB airbag cushion and the IKB cover. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the KAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .

1. Position the Knee AirBag (KAB) to the mounting plate on the instrument panel lower reinforcement.
2. Install and tighten the three nuts that secure the KAB studs to the mounting plate below the instrument panel. Tighten the nuts to 6 N·m (53 in. lbs.).
3. Reconnect the connector insulator of the instrument panel wire harness take out for the KAB to the inflator initiator connector receptacle by pressing straight in on the connector. You can be certain that the connector is fully engaged in its receptacle by listening carefully for a distinct, audible click as the connector latches snap into place.
4. Reinstall the steering column opening cover onto the instrument panel. (Refer to 23 - Body/Instrument Panel/COVER, Steering Column Opening - Installation) .
5. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

OPERATION

The Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB) is deployed by an electrical signal generated by the Occupant Restraint Controller (ORC) to which it is connected through a KAB line 1 (or squib) circuits to the initiator in the airbag inflator. The hybrid-type inflator assembly for the airbag contains a small canister of highly compressed inert gas. When the ORC sends the proper electrical signal to the airbag inflator, the electrical energy creates enough heat to ignite chemical pellets within the inflator.

Once ignited, these chemical pellets burn rapidly and produce the pressure necessary to rupture a containment disk in the inert gas canister. The inflator is sealed to the airbag cushion and a diffuser in the inflator directs all of the inert gas into the airbag cushion, causing the cushion to inflate. As the cushion inflates, the KAB protective cover will split at predetermined tear seam lines concealed on the underside of the cover, then fold open and out of the way.

The cushion protects the lower extremities of the vehicle operator and helps to keep the seat occupant properly positioned for the Driver AirBag (DAB) deployment during a frontal impact collision. Following an airbag deployment, the KAB cushion quickly deflates by venting the inert gas through the loose weave of the fabric used to construct the instrument panel side of the airbag cushion, and the deflated cushion hangs down loosely from the lower instrument panel.

The ORC monitors the condition of the KAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the KAB initiator and squib circuit requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

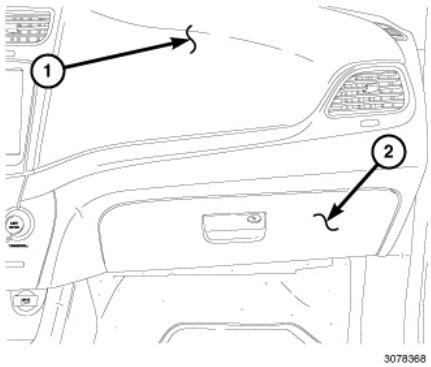
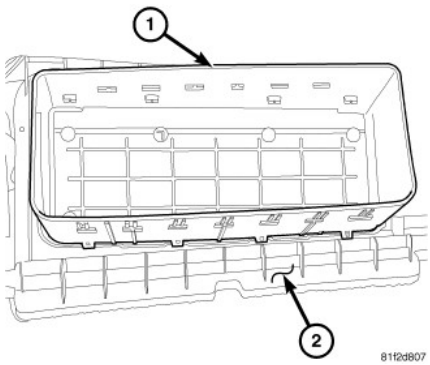
DESCRIPTION

The horizontal surface of the instrument panel top pad (1) above the glove box (2) is the most visible part of the Passenger AirBag (PAB). The PAB door is integral to the top of the instrument panel top pad forward of and above the glove box on the instrument panel in front of the front seat passenger seating position.

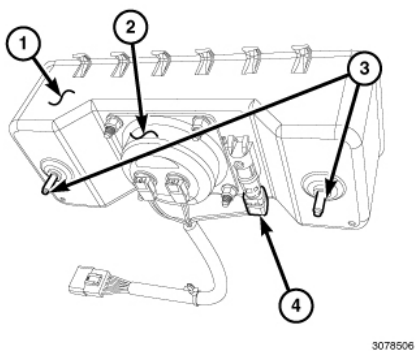


Located below the PAB door area of the instrument panel top pad (2), the molded thermoplastic PAB retainer or chute (1) is secured to the underside of the top pad. The retainer defines the airbag door breakout area of the top pad and serves as the receptacle for the PAB cushion and housing. Numerous small window openings on the forward and rearward flanges of the receptacle receive mating hook formations stamped into the airbag housing, which locate and secure the housing to the top pad.



The PAB unit (1) is also secured by two studs (3) and nuts to a bracket integral to the instrument panel structural support. The PAB unit used in this vehicle is a multistage type that complies with revised federal airbag standards to deploy with less force than those used in some prior vehicles. The PAB unit consists of a stamped metal housing, the airbag cushion, and the airbag inflator (2). The airbag inflator is secured to the housing by four screws and nuts. The airbag housing contains the folded airbag cushion. An approximately 66 centimeter (26 inch) wide by 76 centimeter (30 inch) high rectangular fabric cushion is used.

The airbag inflator is a non-azide, pyrotechnic-type unit that is secured to and sealed within the airbag housing. Two dedicated take outs and yellow connectors of the instrument panel wire harness with keyed, color-coded (black and orange) insulators connect the two inflator initiators to the vehicle electrical system. Vehicles manufactured for domestic markets also include an active vent tether cutter (4) that is connected through a third dedicated take out and connector of the instrument panel wire harness.



The PAB cannot be repaired, and must be replaced if deployed, ineffective, or in any way damaged. The PAB door and retainer are serviced only as a unit with the instrument panel top pad. If the PAB is deployed, the instrument panel top pad must also be replaced.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

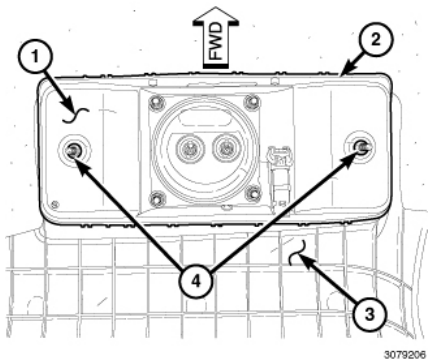
WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the passenger airbag, or becoming entrapped between the passenger airbag cushion and the instrument panel top pad. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

WARNING: **To avoid serious or fatal injury, the instrument panel top pad must never be painted. Replacement top pads are serviced in the original colors. Paint may change the way in which the material of the top pad responds to an airbag deployment. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Passenger AirBag (PAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the PAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Place the instrument panel top pad (3) on a suitable work surface with the Passenger AirBag (PAB) retainer or chute (2) receptacle facing up. Be certain to take the proper precautions to prevent the top pad from receiving cosmetic damage during the following procedures.
2. Carefully position the PAB housing to the PAB retainer or chute receptacle. The side of the housing with 6 hooks faces the defroster duct outlet or forward in the vehicle.
3. Engage all of the hooks on one side of the PAB housing through the windows on the same side of the PAB retainer or chute, then rotate the opposite side of the PAB housing downward into the receptacle.
4. Inspect around the perimeter of the PAB making certain each of the hooks on the PAB housing is fully engaged through the windows in the forward and rearward vertical walls of the PAB retainer or chute receptacle.
5. Reinstall the top pad onto the instrument panel. (Refer to 23 - Body/Instrument Panel/PAD, Instrument Panel - Installation) .
6. Be certain to tighten the nuts that secure the studs (4) of the PAB to the bracket on the instrument panel structural support. Tighten the nuts to 8 N·m (71 in. lbs.).
7. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The multistage Passenger AirBag (PAB) is deployed by electrical signals generated by the Occupant Restraint Controller (ORC) through the PAB squib 1 and squib 2 circuits to the two initiators in the airbag inflator. By using two initiators, the PAB can be deployed at multiple levels of force. The force level is controlled by the ORC to suit the monitored impact conditions by providing one of multiple delay intervals between the electrical signals provided to the two initiators. The longer the delay between these signals, the less forcefully the airbag will deploy.

When the ORC sends the proper electrical signals to each initiator, the electrical energy generates enough heat to initiate a small pyrotechnic charge which, in turn ignites chemical pellets within the inflator. Once ignited, these chemical pellets burn rapidly and produce a large quantity of inert gas. The inflator is sealed to the airbag cushion and a diffuser in the inflator directs all of the inert gas into the airbag cushion, causing the cushion to inflate. As the cushion inflates, the PAB door will split at predetermined tear seam lines concealed on the inside surface of the door, then the door will pivot up over the top of the instrument panel and out of the way. Following an airbag deployment, the airbag cushion quickly deflates by venting the inert gas through a discrete vent hole in each fabric side panel of the airbag cushion.

Domestic market vehicles are equipped with an active vent tether cutter unit. The ORC monitors a seat track position sensor on the passenger front seat. If the seat is in the full forward position when an airbag deployment occurs, the ORC signals the tether cutter to cut the tether that normally keeps active vent flaps in the airbag cushion closed. With the tether cut, the active vents open to reduce airbag deployment force and reduce the possibility of an airbag-induced injury when the passenger is seated close to the deploying airbag. If the passenger front seat is not in the full forward position, the tether is not cut and the active vents in the cushion remain closed during deployment.

Typically, both initiators are used during a PAB deployment event. However, it is possible for only one initiator to be used during a deployment due to an airbag system fault and, it is also possible that the tether cutter was not used during a deployment. It is necessary to always confirm that both initiators and the tether cutter have been used in order to avoid the improper disposal of potentially live pyrotechnic materials. (Refer to 10 - Restraints - Standard Procedure) .

The ORC monitors the condition of the PAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the PAB inflator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

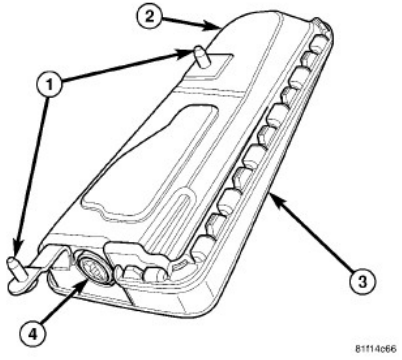
DESCRIPTION

The Seat AirBags (SAB) (also known as pelvic and thoracic airbags) are standard equipment in all markets except Mexico. Vehicles with this equipment can be readily identified by a sewn tag with the **SRS - AIRBAG** logo located on the outboard side of the front seat back trim cover. These airbags are completely concealed beneath the seat back trim cover on the upper outboard sides of both front seat backs. Each SAB unit is inserted into a sewn pouch called an intensifier on the inside of the trim cover, then secured to the seat back frame by nuts on two studs (1). Both studs are installed on a stamped metal bracket. The stud on one end of the bracket exits through the SAB housing (2), while the second stud is located on the opposite end of the bracket that extends from the lower end of the housing.

The folded SAB cushion is contained within and protected by a molded plastic cover (3) secured to the outer edges of the housing. The SAB cushion is constructed of a coated nylon fabric.



The SAB housing contains the airbag inflator and a heat shield. The inflator is a single-initiator, pyrotechnic-type unit that is secured to and sealed within the SAB housing. The SAB is connected to the vehicle electrical system through a dedicated jumper wire harness with a connector insulator that connects directly to the inflator initiator (4). The connector insulators are uniquely keyed and color-coded to ensure they can only be connected to the initiator.

The SAB cannot be repaired, and must be replaced if deployed, ineffective, or in any way damaged. If the SAB is deployed, the seat back frame, the seat back foam cushion, the seat back trim cover and the seat airbag jumper wire harness must also be replaced.

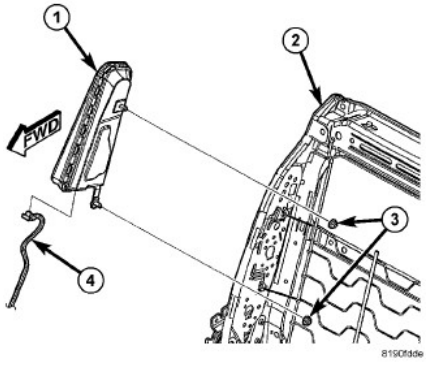
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Seat AirBag (SAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the SAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



CAUTION: **The seat airbag (1) must be installed into the nylon mesh pouch integral to the front seat back trim cover before the airbag or the trim cover are installed on the front seat back frame (2). Failure to do so will adversely affect the function of the seat airbag system.**

1. Carefully slide the Seat AirBag (SAB) into the nylon pouch (intensifier) integral to the outboard side of the front seat back trim cover and engage the two SAB studs through the holes provided in the pouch. Be certain not to tear or damage the nylon pouch or the trim cover.
2. Position the SAB and trim cover as a unit to the outboard side of the seat back frame and insert the studs through the mounting holes in the frame.
3. Install and tighten the two nuts (3) that secure the SAB to the outboard side of the seat back frame. Tighten the nuts to 10 N·m (88 in. lbs.).
4. Reconnect the seat jumper wire harness (4) connector to the SAB inflator. Be certain that the connector latches and lock are fully engaged.

   CAUTION: **Be certain that all of the trim is properly reinstalled on the front seat back frame. Failure to do so will adversely affect the function of the seat airbag system.**

5. Reinstall the trim onto the front and back of the front seat back frame. (Refer to 23 - Body/Seats/COVER, Seat Back - Installation) .
6. Reinstall the front seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .
7. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

Each Seat AirBag (SAB) (also known as a pelvic and thoracic airbag) is deployed individually by an electrical signal generated by the Occupant Restraint Controller (ORC) to which it is connected through left or right SAB line 1 and line 2 (or squib) circuits. The hybrid-type inflator assembly for each SAB contains a small canister of highly compressed inert gas. When the ORC sends the proper electrical signal to the SAB inflator, the electrical energy creates enough heat to ignite chemical pellets within the inflator.

Once ignited, these chemicals burn rapidly and produce the pressure necessary to rupture a containment disk in the inert gas canister. The inflator and inert gas canister are sealed and connected so that all of the released gas is directed into the folded SAB cushion, causing the cushion to inflate. As the cushion inflates it will split the retainer wrap, the sewn pouch (intensifier) and the outboard side of the seat back trim cover and expand into the area between the outboard side of the front seat and the front door to form a cushion to protect the front seat occupant during a side impact collision or a vehicle rollover incident.

Following the SAB deployment, the SAB cushion slowly deflates by venting the inert gas through the loose weave of the cushion fabric, and the deflated cushion hangs down loosely from the outboard side of the front seat back.

The ORC monitors the condition of the SAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the SAB inflator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

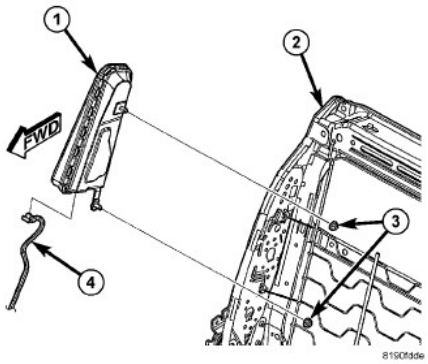
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

NOTE: The following procedure is for replacement of an ineffective or damaged Seat AirBag (SAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the SAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the front seat to its most forward position for easiest access to the front seat mounting hardware.
2. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
3. Remove the front seat from the vehicle. (Refer to 23 - Body/Seats/SEAT - Removal) .

   CAUTION: **During removal of the seat back trim cover, be certain not to tear or damage the integral nylon pouch that contains the seat airbag. If the nylon pouch or the trim cover are torn or damaged, the entire front seat back trim cover must be replaced with a new unit.**

4. Remove the trim from the front and back of the front seat back frame (2), but do not remove from the outboard side of the seat back trim cover until after the Seat AirBag (SAB) has been detached from the seat. (Refer to 23 - Body/Seats/COVER, Seat Back - Removal) .

   CAUTION: **Do not pull on the seat airbag jumper wire harness (4) take out or pry on the connector insulator to disengage the connector from the seat airbag (1) inflator connector receptacle. Improper removal of this take out and its connector insulator can result in damage to the airbag circuits or the connector insulator.**

5. Disconnect the SAB jumper wire harness connector from the SAB inflator. Slide the yellow locking tab down, then squeeze the two latch tabs on the connector insulator. Pull the insulator straight out from the inflator to disconnect it from the connector receptacle.
6. Remove the two nuts (3) that secure the SAB to the side of the seat back frame.
7. Grasp the outboard side of the seat back trim cover and pull the trim cover and cushion over the top of the seat back frame. This will allow room to remove the SAB without damaging the trim cover or the cushion.
8. Working between the seat back trim cover and the seat back frame, carefully disengage the two SAB studs from the nylon pouch (intensifier and slide the SAB

out of the pouch. Be certain not to tear or damage the nylon pouch or the trim cover.

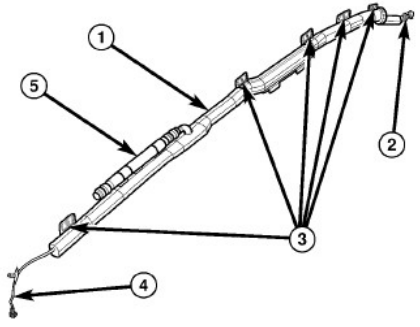
DESCRIPTION

Side curtain airbags (also known as Side AirBag Inflatable Curtains/SABIC) are standard factory installed equipment in this vehicle for all markets except Mexico. These airbags are passive, inflatable, Supplemental Restraint System (SRS) components, and vehicles with this equipment can be readily identified by a molded identification trim button with the **SRS - AIRBAG** logo located near the top of each upper B-pillar and C-pillar trim. This system is designed to reduce injuries to the vehicle occupants in the event of a side impact collision or a vehicle rollover incident.

8098029e

Vehicles equipped with side curtain airbags have two individually controlled curtain airbag units (1). These airbag units are concealed and mounted above the headliner where they are each secured to one of the roof side rails. Each folded airbag cushion is contained within a fabric wrap that extends along the roof rail from the A-pillar at the front of the vehicle to near the D-pillar (5 passenger seating) or to the liftgate opening header (7 passenger seating) at the rear of the vehicle.

Two plastic retainer clips secure a long tether (2) to the inside of the A-pillar downward from the front of the airbag cushion, where it is retained to a slot in the base of the A-pillar near the belt line with a metal hook followed by a plastic push-in retainer to secure the hook in the slot. On vehicles with 5 passenger seating, a retainer clip on another short tether (4) at the rear of the cushion is secured by a screw to the upper liftgate opening header inner reinforcement. On vehicles with 7 passenger seating, the rear of the cushion turns inboard at the D-pillar and is secured by nuts to a weld stud on the upper liftgate opening header inner reinforcement.



81f01e30

The hybrid-type inflator (5) for each airbag is secured to the airbag unit above the C-pillar. A stamped metal bracket on the inflator is secured by two screws to the inner roof rail above the C-pillar. The inflator is connected to the airbag cushion by a tubular manifold. The entire cushion and inflator assembly is temporarily secured through plastic mounting tabs (3) with plastic push-in retainers, then is permanently secured by a combination of screws and nuts to weld studs spaced along the inside of the roof rail.

A take out and connector of the body wire harness is routed up each C-pillar to the roof rail to the connector receptacle of the initiator at the rear of the airbag inflator. This connects the airbag unit to the Occupant Restraint Controller (ORC).

The side curtain airbag unit cannot be adjusted or repaired and must be replaced if deployed, ineffective, or in any way damaged. Once a side curtain airbag has been deployed, the complete airbag unit, the headliner, the upper A, B, C and D-pillar trim, and all other visibly damaged components must be replaced.

INSTALLATION

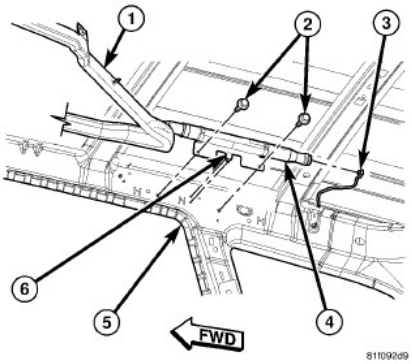
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

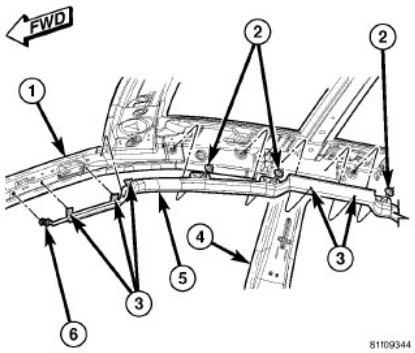
WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the side curtain airbag, or becoming entrapped between the side curtain airbag cushion and the headliner. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the side curtain airbag has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the side curtain airbag (1) and inflator (4) into the vehicle as a unit.
2. Position the inflator mounting bracket to the inner roof rail above the C-pillar (5) and engage the locating tab of the mounting bracket with the locating hole in the roof side rail.
3. Engage the plastic push-in retainer (6) that temporarily secures the inflator mounting bracket to the inner roof rail.
4. Install and tighten the two screws (2) that secure the inflator mounting bracket to the inner roof rail. Tighten the screws to 9 N·m (80 in. lbs.).
5. Reconnect the body wire harness connector (3) to the connector receptacle at the rear of the inflator (2). Be certain to route the wiring outboard of the inflator, between the inflator and the roof side rail.
6. Working from the inflator toward the front of the vehicle, engage the three mounting tabs of the side curtain airbag (5) over the weld studs on the inner roof rail above the rear and front door openings.
7. Working from the inflator toward the front of the vehicle, engage the plastic push-in retainers (3) that temporarily secure the side curtain airbag and the front tether to the inner roof rail over the B-pillar (4) and the inner A-pillar (1).
8. Install and tighten the three nuts (2) that secure the side curtain airbag mounting tabs to the weld studs on the inner roof rail above the front and rear door openings. Tighten the nuts to 9 N·m (80 in. lbs.).
9. Engage the metal hook (6) that secures the front tether to the inner A-pillar near the belt line.

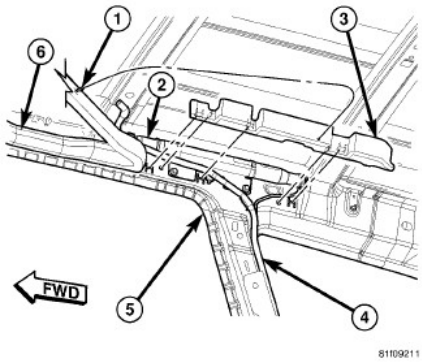
10. Engage the plastic clip that secures the front tether hook to the inner A-pillar. Both the hook and the plastic clip are secured in the same slotted hole of the A-pillar, but the hook MUST be installed prior to the clip.

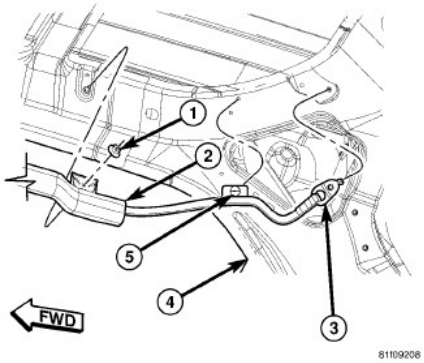


11. Position the Head Impact Countermeasure (HIC) rib cartridge (3) over the airbag inflator (2) above the C-pillar (5) and align the front and rear locating bosses of the cartridge with the slots of the inner roof rail. Be certain the wiring and, if equipped, the sunroof drain hose (4) are routed through the clearance notch at the bottom of the cartridge, between the cartridge and the roof rail.

12. Using hand pressure, press the HIC rib cartridge toward the inner roof rail until the three snap clip retainers snap into place. Be certain the snap clips are fully engaged with the slots in the roof rail.

13. Engage the plastic push-in retainer (1) that secures the side curtain airbag (6) to the HIC rib cartridge.





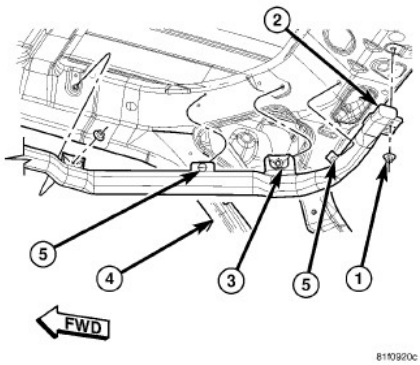
Side Airbag Rear - 5 Passenger Seating

14. Working from the inflator toward the rear of the vehicle, engage the mounting tabs of the side curtain airbag (2) to the weld studs on the inner roof rail above the quarter window opening and, if equipped with seven passenger seating, the upper liftgate opening inner reinforcement.

15. Engage the plastic push-in retainers (5) that temporarily secure the airbag or rear tether mounting tabs to the inner roof rail above the D-pillar (4).

16. Install and tighten the nut (1) that secures the side curtain airbag mounting tab to the weld stud on the inner roof rail above the quarter window opening.

17. On vehicles with 5 passenger seating, install and tighten the screw that secures the rear tether retainer clip (3) to the inner roof rail above the D-pillar (4). Be certain the anti-rotation tab of the retainer clip is engaged in the clearance hole of the roof rail. Tighten the screw to 9



N·m (80 in. lbs.).

Side Airbag Rear - 7 Passenger Seating

18. On vehicles with 7 passenger seating, install and tighten the screw (3) that secures the side curtain airbag mounting tab to the inner roof rail above the D-pillar. Tighten the screw to 9 N·m (80 in. lbs.).

19. On vehicles with 7 passenger seating, install and tighten the nut that secures the side curtain airbag rear mounting tab to the weld stud on the upper liftgate opening inner reinforcement. Tighten the nut to 9 N·m (80 in. lbs.).

20. Reinstall the headliner into the vehicle. (Refer to 23 - Body/Interior/HEADLINER - Installation) .

21. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

OPERATION

Each side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC) is deployed individually by an electrical signal generated by the Occupant Restraint Controller (ORC) to which it is connected through left or right curtain airbag line 1 and line 2 (or squib) circuits. The hybrid-type inflator assembly for each airbag contains a small canister of highly compressed inert gas. When the ORC sends the proper electrical signal to the airbag inflator, the electrical energy creates enough heat to ignite chemical pellets within the inflator.

Once ignited, these chemicals burn rapidly and produce the pressure necessary to rupture a containment disk in the inert gas canister. The inflator and inert gas canister are sealed and connected to a tubular manifold so that all of the released gas is directed into the folded curtain airbag cushion, causing the cushion to inflate. As the airbag cushion inflates it will drop down from the roof rail between the edge of the headliner and the side glass/body pillars to form a curtain-like cushion to protect the vehicle occupants during a side impact collision or a vehicle rollover incident.

The front and rear tethers keep the side airbag cushion taut to the side of the vehicle, while ramps integral to the airbag unit and the adjacent interior trim components direct the inflating cushion downward, ensuring that the airbag will deploy in the proper position. Following the airbag deployment, the airbag cushion slowly deflates by venting the inert gas through the loose weave of the cushion fabric, and the deflated cushion hangs down loosely from the roof rail.

The ORC monitors the condition of the side curtain airbags through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the side curtain airbag inflator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

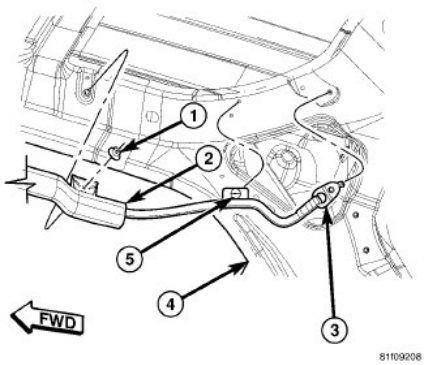
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

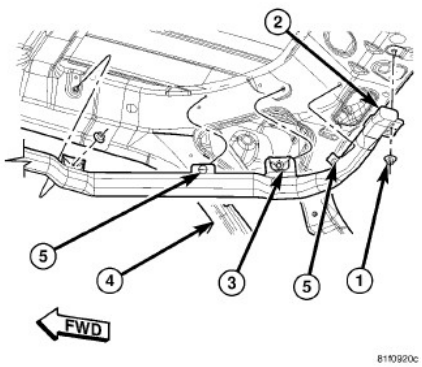
WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the side curtain airbag, or becoming entrapped between the side curtain airbag cushion and the headliner. Failure to observe this warning could result in occupant injuries upon airbag deployment.**



Side Airbag Rear - 5 Passenger Seating

NOTE: The following procedure is for replacement of an ineffective or damaged side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the side curtain airbag has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



Side Airbag Rear - 7 Passenger Seating

1. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Remove the headliner from the vehicle. (Refer to 23 - Body/Interior/HEADLINER - Removal) .
3. On vehicles with 5 passenger seating, remove the screw that secures the side curtain airbag (2) rear tether retainer clip (3) to the inner roof rail above the D-pillar (4).

4. On vehicles with 7 passenger seating, remove the nut (1) that secures the side curtain airbag (2) rear mounting tab to the weld stud on the upper liftgate opening inner reinforcement.

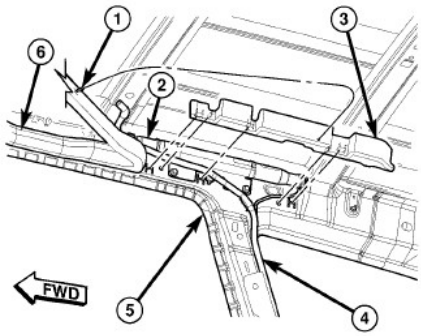
5. On vehicles with 7 passenger seating, remove the screw (3) that secures the side curtain airbag mounting tab to the inner roof rail above the D-pillar (4).

6. Remove the nut (1) that secures the side curtain airbag mounting tab to the weld stud on the inner roof rail above the quarter window opening.

7. Disengage the plastic push-in retainers (5) that secure the airbag or rear tether mounting tabs to the inner roof rail above the D-pillar.

8. Disengage the plastic push-in retainer (1) that secures the side curtain airbag (6) to the Head Impact Countermeasure (HIC) rib cartridge (3) covering the airbag inflator (2) on the inner roof rail above the C-pillar (5).

9. Using a trim stick or another suitable wide flat-bladed tool, carefully pry the HIC rib cartridge away from the inner roof rail far enough to disengage the three snap clip retainers and remove the cartridge from the roof rail. Be certain not to damage the wiring or, if equipped, the sunroof drain hose (4) routed between the cartridge and the roof rail.



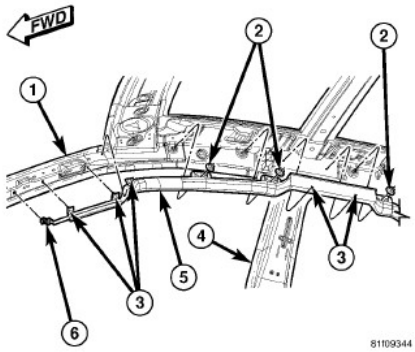
81109211

10. Disengage the plastic clip that secures the side curtain airbag (5) front tether hook (6) to the inner A-pillar (1) near the belt line.

11. Disengage the metal hook that secures the front tether to the inner A-pillar. Both the hook and the plastic clip are secured in the same slotted hole of the A-pillar.

12. Remove the three nuts (2) that secure the side curtain airbag mounting tabs to the weld studs on the inner roof rail above the front and rear door openings.

13. Disengage the plastic push-in retainers (3) that secure the side curtain airbag and the front tether to the inner A-pillar and the inner roof rail over the B-pillar (4).



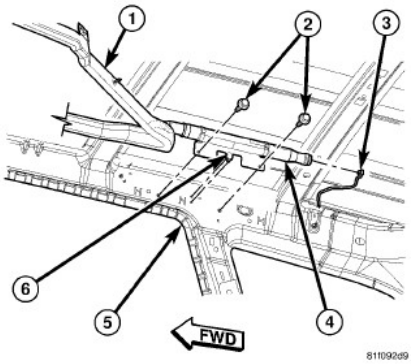
81109344

14. Disconnect the body wire harness connector (3) from the connector receptacle at the rear of the side curtain airbag inflator (4) located on the inner roof rail above the C-pillar (5).

15. Remove the two screws (2) that secure the inflator mounting bracket to the inner roof rail.

16. Disengage the plastic push-in retainer (6) that secures the inflator mounting bracket to the inner roof rail.

17. Remove the side curtain airbag (1) and inflator from the vehicle as a unit.



811092d9

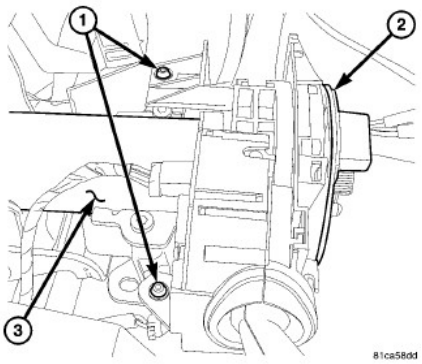
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **If the clockspring is not properly centered in relation to the Steering Angle Sensor (SAS), steering wheel, steering shaft and steering gear, it may be damaged or Diagnostic Trouble Codes (DTC) may be set in the SAS. . Service replacement clocksprings are shipped pre-centered and with a locking pin installed. This locking pin should not be removed until the clockspring has been installed on the steering column.**



1. Reinstall the multi-function switch onto the clockspring. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/SWITCH, Multifunction - Installation) .
2. With the centered clockspring rotor and case secured to each other, or with the plastic locking pin installed, carefully slide the clockspring down over the steering column upper shaft far enough to access and reconnect the following instrument panel wire harness connectors and their wiring retainers to the clockspring, as the vehicle is equipped:
   a. Multi-function switch connector
   b. Steering Angle Sensor (SAS) connector
   c. Two clockspring connectors
   d. Adjustable pedal switch connector, if the vehicle is so equipped.
3. Position the clockspring (2) onto the steering column housing (3).
4. From above the steering column, install and tighten the two captive screws (1) that secure the back of the clockspring to the steering column. Tighten the screws to 3 N·m (25 in. lbs.).
5. Install and tighten the screw (2) on the face of the clockspring that secures the clockspring (1) to the steering column. Tighten the screw to 3 N·m (25 in. lbs.).
6. Reinstall the upper and lower shrouds onto the steering column housing. (Refer to 19 - Steering/Column/SHROUD, Steering Column - Installation) .
7. Reinstall the steering wheel onto the steering column. (Refer to 19 - Steering/Column/WHEEL, Steering - Installation) .

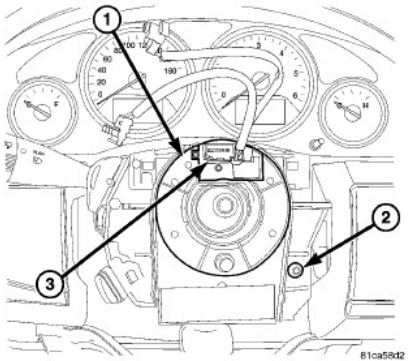
NOTE: When reinstalling the steering wheel, be certain to index the engagement dowel/drive pin on the upper surface of the clockspring rotor with the slot cast into the lower surface of the steering wheel armature hub.

8. Remove the plastic locking pin or any other device that is being used to secure the clockspring rotor to the clockspring case to maintain clockspring centering.

9. Reconnect the steering wheel wire harness connector to the upper clockspring connector receptacle. Be certain that the steering wheel wire harness is routed between the steering wheel back trim cover and the steering wheel armature.

10. Reinstall the Driver AirBag (DAB) onto the steering wheel. (Refer to 10 - Restraints/AIR BAG, Driver - Installation) .

11. Reconnect the negative cable to the battery.



NOTE:

Proper clockspring installation must also be confirmed by viewing the SAS Menu Item, Data Display function using a diagnostic scan tool.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The clockspring is a mechanical electrical circuit component that is used to provide continuous electrical continuity between the fixed instrument panel wire harness and the electrical components mounted on or in the rotating steering wheel. On this vehicle the rotating electrical components include the Driver AirBag (DAB), the horn switch, the speed control switch, the remote radio switches and the Electronic Vehicle Information Center (EVIC) control switches, if the vehicle is so equipped. The clockspring case is positioned and secured near the top of the steering column. The fixed connector receptacles on the back of the fixed clockspring case connect the clockspring to the vehicle electrical system through take outs with connectors from the instrument panel wire harness.

The turn signal cancel cam is integral to the rim of the clockspring rotor hub within the clockspring case so it also moves with the rotation of the steering wheel. Two short pigtail wires on the upper surface of the clockspring rotor connect the clockspring to the DAB, while a steering wheel wire harness connected to the connector receptacle on the upper surface of the clockspring rotor completes circuits to the horn switch, the speed control switch and, if the vehicle is so equipped, to the optional remote radio switches and EVIC control switch on the steering wheel. Another connector receptacle is dedicated to the inputs and outputs of the Local Interface Network (LIN) data bus master node and Controller Area Network (CAN) data bus gateway integral to the Steering Angle Sensor (SAS) on the back of the clockspring case.

The clockspring tape has travel limits and will be damaged by being wound too tightly during full stop-to-stop steering wheel rotation. To prevent this from occurring, the clockspring is centered when it is installed on the steering column. Centering the clockspring indexes the clockspring tape and the SAS integral to the clockspring to the movable steering components so that the tape can operate within its designed travel limits and the SAS can accurately monitor and communicate steering wheel inputs. However, if the clockspring is removed from the steering column or if the steering shaft is disconnected from the steering gear, the clockspring spool and the SAS can change position relative to the movable steering components and relative to each other. The clockspring must be replaced if proper centering has been compromised or the tape may be damaged and Diagnostic Trouble Codes (DTC) or faults may be set within the SAS.

Service replacement clocksprings are shipped pre-centered and with a plastic locking pin installed. This locking pin should not be removed until the clockspring and the steering wheel have been installed on the steering column. If the locking pin is removed before the clockspring is properly installed, the clockspring must be replaced with a new unit. Proper clockspring installation must also be confirmed by viewing the SAS Menu Item, Data Display function using a diagnostic scan tool.

The hard wired clockspring circuits as well as the hard wired input and output circuits of the SAS may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the SAS or the electronic controls and communication between the SAS and other modules and devices. The most reliable, efficient and accurate means to diagnose the SAS or the electronic controls and communication related to clockspring or SAS operation requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

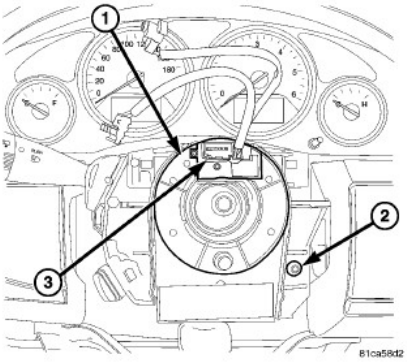
REMOVAL

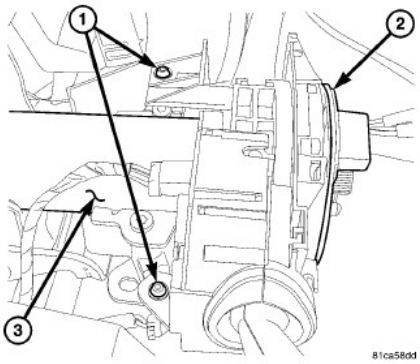
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **Always turn the steering wheel until the front wheels are in the straight-ahead position. Then, prior to removing the clockspring from the steering column or disconnecting the steering column from the steering gear, lock the steering wheel to the steering column or securely fasten the clockspring rotor to the clockspring case. If clockspring centering has been compromised for ANY reason, the entire clockspring and Steering Angle Sensor (SAS) unit MUST be replaced with a new unit.**



1. Place the front wheels in the straight ahead position.
2. Disconnect and isolate the negative cable from the battery.
3. Remove the Driver AirBag (DAB) from the steering wheel. (Refer to 10 - Restraints/AIR BAG, Driver - Removal) .
4. Disconnect the steering wheel wire harness connector from the upper clockspring connector receptacle (3).
5. Remove the steering wheel from the steering column. (Refer to 19 - Steering/Column/WHEEL, Steering - Removal) .
6. If the removed clockspring (1) is to be reused, be certain to secure the clockspring rotor to the clockspring case to maintain clockspring centering until the steering wheel is reinstalled on the steering column. If clockspring centering is not maintained, the clockspring and Steering Angle Sensor (SAS) unit must be replaced with a new unit. (Refer to 10 - Restraints/CLOCKSPRING - Standard Procedure) .
7. Remove the upper and lower shrouds from the steering column. (Refer to 19 - Steering/Column/SHROUD, Steering Column - Removal) .
8. Remove the screw (2) from the face of the clockspring that secures the clockspring to the steering column.
9. From above the steering column (3), fully loosen the two captive screws (1) that secure the back of the clockspring (2) to the steering column housing. These screws are captive and will remain with the clockspring after it is removed from the steering column.



10. Pull the clockspring rearward away from the top of the steering column far enough to access and disconnect the following instrument panel wire harness connectors and their wiring retainers from the clockspring, as the vehicle is equipped:
    a. Multi-function switch connector
    b. Steering Angle Sensor (SAS) connector

c. Two clockspring connectors

d. Adjustable pedal switch connector, if the vehicle is so equipped.

11. Remove the clockspring from the steering column. The clockspring cannot be repaired. It must be replaced if ineffective, damaged, centering has been compromised or the DAB has been deployed.

12. Remove the multi-function switch from the clockspring. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/SWITCH, Multifunction - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

STANDARD PROCEDURE - CLOCKSPRING CENTERING

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **Always turn the steering wheel until the front wheels are in the straight-ahead position. Then, prior to removing the clockspring from the steering column or disconnecting the steering column from the steering gear, lock the steering wheel to the steering column or securely fasten the clockspring rotor to the clockspring case. If clockspring centering has been compromised for ANY reason, the entire clockspring and Steering Angle Sensor (SAS) unit MUST be replaced with a new unit.**

Like the clockspring in a timepiece, the clockspring tape has travel limits and can be damaged by being wound too tightly during full stop-to-stop steering wheel rotation. To prevent this from occurring, the clockspring is centered when it is installed on the steering column. Centering the clockspring indexes the clockspring tape and the SAS integral to the clockspring to the movable steering components so that the tape can operate within its designed travel limits and the SAS can accurately monitor and communicate steering wheel inputs.

However, if the clockspring is removed from the steering column or if the steering shaft is disconnected from the steering gear, the clockspring spool and the SAS can change position relative to the movable steering components and relative to each other. The clockspring must be replaced if proper centering has been compromised or the tape may be damaged and Diagnostic Trouble Codes (DTC) or faults may be set within the SAS.

Service replacement clocksprings are shipped pre-centered and with a plastic locking pin installed. This locking pin should not be removed until the clockspring and the steering wheel have been installed on the steering column. If the locking pin is removed before the clockspring is installed on a steering column, the clockspring and SAS must be replaced with a new unit. Proper clockspring installation must also be confirmed by viewing the SAS Menu Item, Data Display function using a diagnostic scan tool.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

ACTIVE RESTRAINTS

The active restraints for this vehicle include:

- **Child Restraint Anchors** - All vehicles are equipped with three, fixed-position, child seat upper tether anchors for the second row seat. Two anchors are integral to the back of the right second row seat cushion frame, and one is integral to the left second row seat cushion frame. The upper tether anchors are accessed from behind the second row seats. Two lower anchors are also provided for each outboard second row seating position, while only one lower anchor is provided for the center seating position. These lower anchors are also integral to the second row seat cushion frames. The lower anchors are all accessed from the front of the second row seats, where the seat back meets the seat cushion.
- **Front Seat Belts** - Both front seating positions are equipped with three-point seat belt systems employing lower B-pillar mounted inertia latch-type emergency locking retractors, height-adjustable upper B-pillar mounted turning loops, a traveling lower seat belt anchor secured to the outboard side of the seat frame, and a traveling end-release seat belt buckle secured to the inboard side of the seat frame. The passenger side front seat belt retractor is switchable to an automatic locking retractor for compatibility with child seats. The driver and passenger side front seat belt buckles each include an integral seat belt switch that detects whether the front seat belts have been fastened.
- **Integrated Child Booster Seats** - Two integrated child booster seats are an available option. Vehicles with this option have a booster seat integral to each of the two outboard second row seating positions. The center section of the seat cushion of these seats is lifted up and rearward to raise the seat cushion. These booster seats raise a child aged four and older, weighing over 18.14 kilograms (40 pounds) and up to 144.78 centimeters (57 inches) tall into the belted zone of the adult seat belts.
- **Second Row Seat Belts** - All second row seating positions are equipped with three-point seat belt systems. The outboard seating position belts employ C-pillar mounted inertia latch-type emergency locking retractors, fixed position upper C-pillar mounted turning loops and fixed lower seat belt anchors secured to the floor panel. The second row center seating position belt has an inertia latch-type emergency locking retractor that is integral to the right second row seat back panel. The second row center seating position belt lower anchor is secured to the second row right seat cushion frame. All three rear seat belts have fixed end-release seat belt buckles secured to the seat cushion frames, a double buckle unit on the left side and a single buckle unit on the right side. Both outboard second row seat belt retractors are switchable to an automatic locking retractor for compatibility with child seats.
- **Third Row Seat Belts** - In vehicles equipped with the optional third row bench seat, both third row seating positions are equipped with three-point seat belt systems. These belts employ lower D-pillar mounted inertia latch-type emergency locking retractors, fixed position upper D-pillar mounted turning loops, fixed lower seat belt anchors and fixed position end-release buckles secured to the floor panel. Both third row seat belt retractors are switchable to an automatic locking retractor for compatibility with child seats.

SUPPLEMENTAL RESTRAINT SYSTEM

A Supplemental Restraint System (SRS) is standard factory-installed safety equipment on this vehicle. Available supplemental occupant restraints for this vehicle include both active and passive types. Active restraints are those which require the vehicle occupants to take some action to employ, such as fastening a seat belt; while passive restraints require no action by the vehicle occupants to be employed.

In addition, vehicles manufactured for certain export markets include the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System), which includes both dynamic and static elements designed to enhance the protection of pedestrians. Additional information on each of these subsystems of the SRS can be found elsewhere within this service information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

ACTIVE RESTRAINTS

The primary passenger restraints in this or any other vehicle are the standard equipment factory-installed seat belts and child restraint anchors. Seat belts and child restraint anchors are referred to as an active restraint because the vehicle occupants are required to physically fasten and properly adjust these restraints in order to benefit from them.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

SUPPLEMENTAL RESTRAINT SYSTEM

The Supplemental Restraint System (SRS) is comprised of two primary subsystems: Active Restraints and Passive Restraints. In addition, vehicles manufactured for certain export markets include the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System), which includes both dynamic and static elements designed to enhance the protection of pedestrians. Additional operational details on each of these subsystems of the SRS can be found elsewhere within this service information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

SERVICE AFTER A SUPPLEMENTAL RESTRAINT SYSTEM DEPLOYMENT

Any vehicle which is to be returned to use following a Supplemental Restraint System (SRS) component deployment must have the deployed restraints replaced. In addition, the following guidelines MUST be observed.

- **Following ANY major vehicle impact damage in the vicinity of an impact sensor or the ORC** - It is critical that the mounting surfaces and mounting brackets for the Occupant Restraint Controller (ORC), front impact sensors and side impact sensors located within the proximity of the impact damage be closely inspected and restored to their original conditions. Because the ORC and each impact sensor are used by the SRS to monitor or confirm the direction and severity of a vehicle impact, improper orientation or insecure fastening of these components may cause airbags not to deploy when required, or to deploy when not required.
- **If an active head restraint is deployed** - Deployed Active Head Restraint (AHR) units that are undamaged are designed with the intention of reuse. However, the deployed AHR units must be properly reset following deployment. (Refer to 10 - Restraints/RESTRAINT, Active Head - Standard Procedure) .
- **If the driver airbag is deployed** - If the Driver AirBag (DAB) has been deployed, the clockspring and the steering column must be replaced.
- **If the knee airbag is deployed** - On vehicles so equipped, if the Knee AirBag (also known as the Inflatable Knee Blocker/IKB) has been deployed, the instrument panel steering column opening cover must also be replaced.
- **If the passenger airbag is deployed** - If the Passenger AirBag (PAB) has been deployed, the instrument panel top pad must also be replaced.
- **If a seat airbag is deployed** - If a Seat AirBag (SAB) (also known as the pelvic and thoracic airbags) has been deployed, the seat back frame, the seat back foam and the seat back trim cover on the same side of the vehicle as the deployed airbag must also be replaced.
- **If a seat belt tensioner is deployed** - The seat belt tensioners are deployed in conjunction with the front airbags, but can also be deployed with a Seat AirBag (SAB) (also known as the pelvic and thoracic airbag) or side curtain airbags (also known as Side AirBag Inflatable Curtain/SABIC). The seat belt tensioners must be replaced if either front airbag has been deployed, and must be inspected if either SAB or side curtain airbag has been deployed.
- **If a side curtain airbag is deployed** - If a side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC) has been deployed, the headliner as well as the upper A, B, C and, on vehicles with the optional seven-passenger seating, the D-pillar trim on the same side of the vehicle as the deployed airbag must also be replaced. On vehicles with an optional sunroof, the sunroof drain tubes and hoses must be closely inspected following a side curtain airbag deployment.

The components identified with the deployed SRS components in the preceding list are not intended for reuse and will be damaged or weakened as a result of an airbag deployment, which may or may not be obvious during a visual inspection. All other vehicle components should be closely inspected following any SRS component deployment, but are to be replaced only as required by the extent of the visible damage incurred.

SQUIB CIRCUIT DAMAGE

In addition to the preceding guidelines, be aware that the heat created by the initiator during an airbag or tensioner deployment will cause collateral damage to the connected wiring (squib circuits) and connector insulators. There are two methods by which an airbag or seat belt tensioner may be connected to the vehicle electrical system. The first method involves a short pigtail harness and connector insulator that are integral to the airbag or tensioner unit and are replaced as a unit with the service replacement airbag or seat belt tensioner. This connection method typically requires no additional wiring repair following a deployment.

However, the second connection method involves a wire harness takeout and connector insulator that are connected directly to the airbag or tensioner initiator or squib. These direct-connect type take outs and connector insulators **MUST** be repaired following an airbag or seat belt tensioner deployment using the approved Supplemental Restraint System Wiring Repairs procedure. (Refer to 10 - Restraints - Standard Procedure) .

AIRBAG SQUIB STATUS

Multistage airbags with multiple initiators (squibs) must be checked to determine that all squibs were used during the deployment event. The Driver AirBag (DAB) and Passenger AirBag (PAB) in this vehicle are deployed by electrical signals generated by the Occupant Restraint Controller (ORC) through the driver or passenger squib 1 and squib 2 circuits to the two initiators in the airbag inflators. Typically, both initiators are used and all potentially hazardous chemicals are burned during an airbag deployment event. However, it is possible for only one initiator to be used; therefore, it is always necessary to confirm that both initiators have been used in order to avoid the improper handling or disposal of potentially live pyrotechnic or hazardous materials. The following procedure should be performed using a diagnostic scan tool to verify the status of both airbag squibs before either deployed airbag is removed from the vehicle for disposal.

CAUTION: **Deployed front airbags having two initiators (squibs) in the airbag inflator may or may not have live pyrotechnic material within the inflator. Do not dispose of these airbags unless you are certain of complete deployment. Refer to the Hazardous Substance Control System for information regarding the potentially hazardous properties of the subject component and the proper safe handling procedures. Then dispose of all non-deployed and deployed airbags and seat belt tensioners in a manner consistent with state, provincial, local and federal regulations.**

1. Be certain that the diagnostic scan tool contains the latest version of the proper diagnostic software. Connect the scan tool to the 16-way Data Link Connector (DLC). The DLC is located on the driver side lower edge of the instrument panel, outboard of the steering column.
2. Transition the status of the ignition switch to On.
3. Using the scan tool, read and record the active (current) Diagnostic Trouble Code (DTC) data.

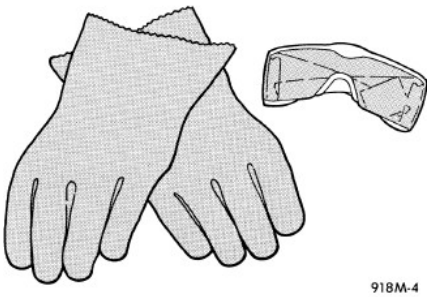
Using the active DTC information, refer to the **Airbag Squib Status** table to determine the status of both DAB squibs and both PAB squibs.

AIRBAG SQUIB STATUS		
IF THE ACTIVE DTC IS:	CONDITIONS	SQUIB STATUS
Driver or Passenger Squib 1 open Driver or Passenger Squib 2 open	**AND** the stored DTC minutes for both Driver or Passenger squibs are within 15 minutes of each other	Both Squib 1 and 2 were used.
Driver or Passenger Squib 1 open Driver or Passenger Squib 2 open	**AND** the stored DTC minutes for Driver or Passenger Squib 2 open is GREATER than the stored DTC minutes for Driver or Passenger Squib 1 by 15 minutes or more	Squib 1 was used; Squib 2 is live.
Driver or Passenger Squib 1 open Driver or Passenger Squib 2 open	**AND** the stored DTC minutes for Driver or Passenger Squib 1 open is GREATER than the stored DTC minutes for Driver or Passenger Squib 2 by 15 minutes or more	Squib 1 is live; Squib 2 was used.
Driver or Passenger Squib 1 open	**AND** Driver or Passenger Squib 2 open is NOT an active code	Squib 1 was used; Squib 2 is live.
Driver or Passenger Squib 2 open	**AND** Driver or Passenger Squib 1 open is NOT an active code	Squib 1 is live; Squib 2 was used.

NOTE: If none of the Driver or Passenger Squib 1 or 2 open are active codes, the status of the airbag squibs is unknown. In this case the airbag should be handled and disposed of as if the squibs were both live.

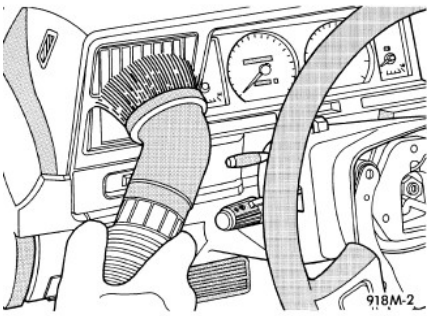
CLEANUP PROCEDURE

Following a Supplemental Restraint System (SRS) component deployment, the vehicle interior will contain a powdery residue. This residue consists primarily of harmless particulate by-products of the small pyrotechnic charge that initiates the propellant used to deploy a SRS component. However, this residue may also contain traces of sodium hydroxide powder, a chemical by-product of the propellant material that is used to generate the inert gas that inflates the airbag. Since sodium hydroxide powder can irritate the skin, eyes, nose, or throat, be certain to wear safety glasses, rubber gloves, and a long-sleeved shirt during cleanup.



WARNING: **To avoid serious or fatal injury, if you experience skin irritation during cleanup, run cool water over the affected area. Also, if you experience irritation of the nose or throat, exit the vehicle for fresh air until the irritation ceases. If irritation continues, see a physician.**

1. Begin the cleanup by using a vacuum cleaner to remove any residual powder from the vehicle interior. Clean from outside the vehicle and work your way inside, so that you avoid kneeling or sitting on a non-cleaned area.
2. Be certain to vacuum the heater and air conditioning outlets as well. Run the heater and air conditioner blower on the lowest speed setting and vacuum any powder expelled from the outlets.



CAUTION: **Deployed front airbags having two initiators (squibs) in the airbag inflator may or may not have live pyrotechnic material**

within the inflator. Do not dispose of these airbags unless you are certain of complete deployment. Refer to the AIRBAG SQUIB STATUS heading within this information. All damaged, ineffective, or non-deployed Supplemental Restraint System (SRS) components which are replaced on vehicles are to be handled and disposed of properly. If an airbag or seat belt tensioner unit is ineffective or damaged and non-deployed, refer to the Hazardous Substance Control System for information regarding the potentially hazardous properties of the subject component and the proper safe handling procedures. Then dispose of all non-deployed and deployed airbags and seat belt tensioners in a manner consistent with state, provincial, local and federal regulations.

3. Next, remove the deployed SRS components from the vehicle. Refer to the appropriate service removal procedures.

4. You may need to vacuum the interior of the vehicle a second time to recover all of the powder.

SUPPLEMENTAL RESTRAINT STORAGE

Airbags and seat belt tensioners must be stored in their original, special container until they are used for service. Also, they must be stored in a clean, dry environment away from sources of extreme heat, sparks and high electrical energy. Always place or store any airbag on a surface with its trim cover or airbag cushion side facing up, to minimize movement in case of an accidental deployment.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

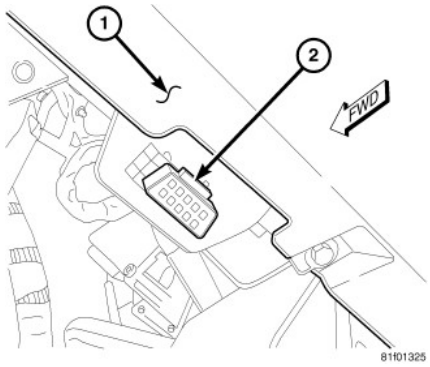
SUPPLEMENTAL RESTRAINT SYSTEM VERIFICATION TEST

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: The following procedure should be performed using a diagnostic scan tool to verify proper Supplemental Restraint System (SRS) operation following the service or replacement of any SRS component. Refer to the appropriate diagnostic procedures.



1. During the following test, the negative cable remains disconnected and isolated from the battery, as it was during the Supplemental Restraint System (SRS) component removal and installation procedures.
2. Be certain that the diagnostic scan tool contains the latest version of the proper diagnostic software. Connect the scan tool to the 16-way Data Link Connector (DLC) (2). The DLC is located on the driver side lower edge of the instrument panel within a rectangular cutout in the lower instrument panel reinforcement, just forward of the instrument panel steering column opening cover (1).
3. Transition the status of the ignition switch to On and exit the vehicle with the scan tool.
4. Check to be certain that nobody is in the vehicle, then reconnect the negative cable to the battery.
5. Using the scan tool, read and record the active (current) Diagnostic Trouble Code (DTC) data.
6. Next, use the scan tool to read and record any stored (historical) DTC data.
7. If any DTC is found in Step 5 or Step 6, refer to the appropriate diagnostic information.
8. Use the scan tool to erase the stored DTC data. If any problems remain, the stored DTC data will not erase. Refer to the appropriate diagnostic information to diagnose any stored DTC that will not erase. If the stored DTC information is successfully erased, go to Step 9.
9. Transition the status of the ignition switch to Off for about 15 seconds, and then back to On. Observe the airbag indicator in the instrument cluster. It should light from four to six seconds, and then go out. This indicates that the SRS is functioning normally and that the repairs are complete. If the airbag indicator fails to light, or lights and stays On, there is still an active SRS fault or malfunction. Refer to the appropriate diagnostic information to diagnose the problem.

SUPPLEMENTAL RESTRAINT SYSTEM WIRING REPAIRS

Special Tools: Click to display a list of tools used in this procedure

It is important when repairing any Supplemental Restraint System (SRS) electrical circuits to use the recommended splicing kit and procedure. For applicable and available MOPAR wiring repair kits, please visit the MOPAR Connector Web Site at the following address on the internet: (http://dto.vftis.com/mopar/disclaimer.asp).

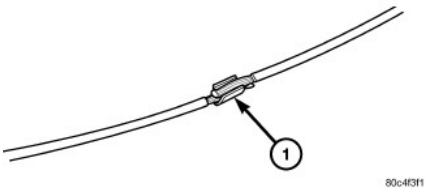
This recommended procedure involves crimping the wires together with a splice band, soldering the crimped connection and, finally, sealing and protecting the repair. The crimp and solder ensure a strong mechanical bond that will always pass a pull test while also maintaining the conductivity and current carrying capacity of the circuit. The adhesive sealant and heat shrink tubing ensures the splice repair will perform as well or better than the original wire and be safe from potential corrosion or short circuits.

There is no limit to the number of splice repairs that can be made in one harness using this procedure. However, as has been past practice, multiple adjacent splices should be offset from each other. This wiring splice repair procedure is approved for harness side repairs only. Repairs and splices to pigtail wires on SRS components such as airbag units, seat belt tensioner units or clocksprings are not approved or recommended.

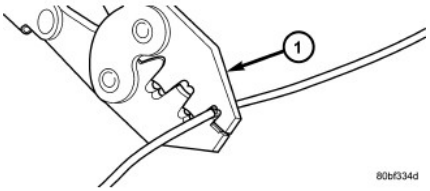
REPAIR PROCEDURE

CAUTION: **If additional wire is needed when making a splice repair to any wire, it is important that the same or next larger size wire gauge be used. Refer to the appropriate wiring diagram for the original wire gauge size.**

1. Remove 13 millimeters (0.50 inch) of insulation from each wire that needs to be spliced.
2. Place a piece of adhesive sealant-lined heat shrink tubing (Part Number 04778570 or equivalent) over the wire on one side of the splice. Be certain the length of tubing will be sufficient to cover and seal the entire repair area.
3. Place the strands of the wires being spliced so that they are overlapping each other within the splice band (1).

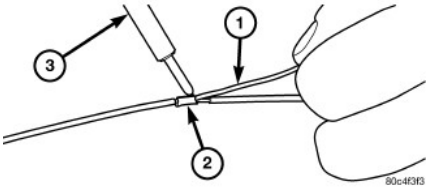


4. Using a crimping tool (1) (MOPAR Part Number 05019912AA, Miller Special Tool Number 10042 or equivalent) crimp the splice band and wires together securely.



CAUTION: **Never use acid core solder for electrical wiring repairs.**

5. Using rosin core type solder (1) only and a suitable soldering iron (3), solder the wire and splice band connection (2) together.



6. Center the heat shrink tubing (2) over the splice joint repair and heat using a suitable heat gun. Heat the joint until the tubing is tightly sealed and sealant (1) begins to ooze out of both ends of the tubing.

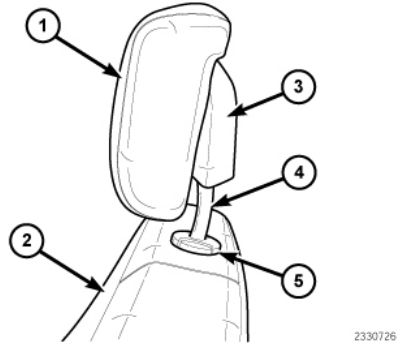
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Active Head Restraint (AHR) units are standard equipment for both front seating positions in this vehicle. One AHR unit is located atop each front seat back (2). An AHR can be readily distinguished from a non-active head restraint by the two-piece construction used for an AHR. The forward-facing pad (1) consists of a molded reinforced plastic convex form covered with a dense foam pad and is trimmed in a material coordinated with the other soft trim on the seat. The rearward-facing surface is equipped with a hard molded plastic trim cover (3) that matches the other hard trim on the seat.

Located between the pad and the trim cover are the support structure of the AHR and both the mechanical and electrical components of the unit. The support structure includes a molded plastic carrier that is securely clamped to a U-shaped, bright-plated metal tube, the legs of which form the two visible posts (4) that are used to secure the unit in the two plastic guide sleeves (5) located at the top of the seat back frame. These posts feature numerous notches that engage spring-loaded detents integral to the plastic guide sleeves which are used for manually adjusting the vertical height of the AHR unit to properly fit the seat occupant.



The mechanical components of the AHR include the linkage that permits the lower part of the pad to be tilted forward or rearward for comfort as well as the linkage that articulates the pad during deployment, a pair of heavy wire springs, a caliper-type latch mechanism and the latch striker. The single electrical component of the AHR unit is a latch-release solenoid and the pigtail wire that connects the solenoid to the vehicle electrical system. The pigtail wire and connector are routed through the center of one of the support posts and down through the guide sleeve into the interior of the seat back, where it is connected to a dedicated take out and connector of the seat wire harness.

The AHR cannot be repaired. If damaged or ineffective, it must be replaced with a new unit. However, unlike many other Supplemental Restraint System (SRS) components, following an AHR deployment, if no visible damage to the unit is observed it can usually be successfully reset and reused. (Refer to 10 - Restraints/RESTRAINT, Active Head - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Active Head Restraint (AHR) units are deployed by a signal generated by the Occupant Restraint Controller (ORC) through the first row right and left solenoid and ground signal circuits. The ORC logic monitors inputs from the front impact sensors as well as electronic message inputs received over the Controller Area Network (CAN) data bus to determine when the appropriate conditions exist to send a deployment signal to both AHR units. When the ORC detects an impact pulse of sufficient magnitude originating from the rear of the vehicle, while any transmission gear is selected except Reverse (**R**), the ORC sends the deployment signals.

When the ORC sends the proper electrical deployment signal to the solenoid of the AHR unit, the solenoid releases the AHR latch. When the AHR latch is released, the tension of the spring-loaded linkage within the AHR mechanically drives the AHR pad through a short, slightly forward and upward arc to the final deployed position. Deployment of the AHR reduces the space between the back of the head of the seat occupant and the head restraint pad. Closing this space supports the head of the seat occupant during a low speed rear impact collision event and is important in reducing or eliminating potentially debilitating cervical (also known as whiplash) injuries.

The ORC monitors the condition of the AHR unit circuits, and will illuminate the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and store a Diagnostic Trouble Code (DTC) for any fault that is detected.

The hard wired circuits between the AHR units and the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the AHR units or the electronic controls and communication between other modules and devices that provide some features of the Supplemental Restraint System (SRS). The most reliable, efficient and accurate means to diagnose the AHR units or the electronic controls and communication related to AHR unit operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

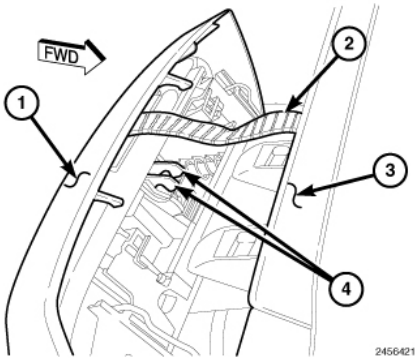
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

STANDARD PROCEDURE - ACTIVE HEAD RESTRAINT RESET

If the Active Head Restraint (AHR) units have been deployed, both the driver and passenger side units must be reset. You can recognize that an AHR has been deployed by the forward position of the head restraint cushion and the large spacing between the cushion and the AHR rear trim cover.

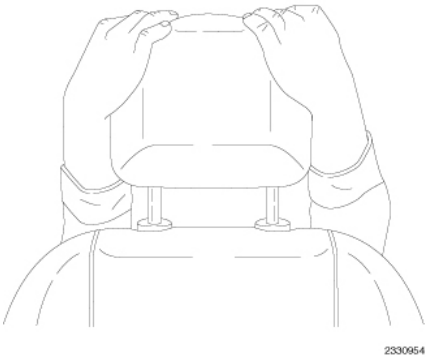


NOTE:

Before attempting to reset, and after each unsuccessful attempt to reset an AHR, inspect the latch mechanism within the AHR rear trim cover (1) to be certain the latch is unlatched. This can be confirmed by placing a finger on the latch catches (4) and gently rocking them rearward and forward. The catches should move freely. If the catches do not move freely, they are in the latched position and the latch must be opened using the diagnostic scan tool. Follow the steps outlined for AHR - Activate Driver And Passenger Head Restraint under System Test for the Occupant Restraint Controller/ORC menu item. Each time this routine is performed, both the driver and passenger side AHR unit latches may be opened and both AHR units may have to be reset.

1. Be certain to pull the center of AHR tether strap (2) located between the rear trim cover and the cushion (3) upward as far as possible to prevent it from becoming trapped between the latch striker and the latch catches, which could interfere with successful latching of the striker.

2. Reaching from behind the seat and below the AHR, position both hands on the top of the AHR cushion as illustrated and brace your forearms or your upper torso against the upper seat back as needed for leverage.



3. Three separate and distinct physical actions must each be completed in their entirety to successfully reset and latch an AHR. It may help to memorize these actions before attempting the reset as: **DOWN**, **BACK** and **DOWN**. A short explanation of each action follows:

   a. **DOWN**: Pull the cushion downward (arrow a) far enough to allow the AHR linkage to drop out of its locked, deployed position to its neutral position. The cushion cannot be compressed against the rear trim cover until after the AHR linkage has been moved to its neutral position.

   b. **BACK**: Pull the cushion rearward (arrow b) firmly and evenly against the pressure of the deployment springs until it is flush against the rear trim cover.

   c. **DOWN**: Finally, while still holding the cushion tightly against the rear trim cover, pull the cushion downward (arrow c) once again far enough to fully engage the latch striker with the AHR latch mechanism. Listen for an audible click as the latch catches engage the striker.

4. If the tether remains hanging out between the top of the cushion and the rear trim cover, simply use a finger to tuck it out of sight between the top of the rear trim cover and the cushion.

5. To confirm a successful reset, there should be no visually obvious space between the cushion and the rear trim cover; although, there may be enough space to physically insert your fingertips between them. Also, operation of the comfort tilt adjustment feature should be restored.

ASSEMBLY

Labor Operations: Click to display a list of Labor Operations associated with this procedure

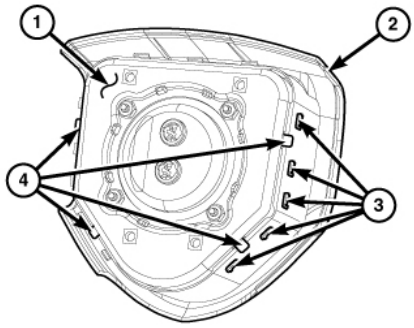
WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, service of this unit should be performed only by Chrysler-trained and authorized dealer service technicians. Failure to take the proper precautions or to follow the proper procedures could result in accidental, incomplete, or improper airbag deployment and possible occupant injuries.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the Driver AirBag (DAB), or becoming entrapped between the DAB cushion and the DAB trim cover. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

WARNING: **To avoid serious or fatal injury, the Driver AirBag (DAB) trim cover must never be painted. Replacement trim covers are serviced in the original colors. Paint may change the way in which the material of the trim cover responds to an airbag deployment. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

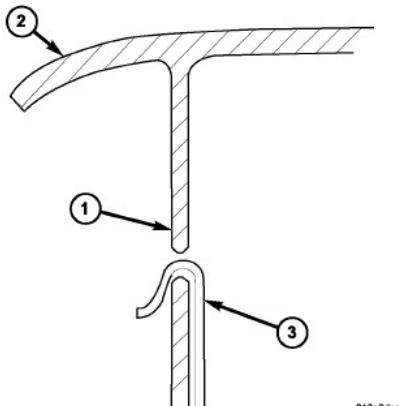
NOTE: The following procedures can be used to replace the Driver AirBag (DAB) trim cover for service of cosmetic damage issues. If the DAB is ineffective or deployed, the entire DAB and trim cover must be replaced as a unit.



2939410

1. Place the Driver AirBag (DAB) trim cover (2) on a suitable clean and dry work surface with the receptacle facing up. Be certain to take the proper precautions to prevent the trim cover from receiving cosmetic damage during the following procedures.
2. Position the DAB housing (1), inflator, and cushion as a unit over the trim cover receptacle.
3. Using hand pressure, push the airbag housing firmly and evenly down into the trim cover receptacle far enough that the hooks (3) of the housing are aligned with the windows in the vertical walls of the receptacle.
4. Work around the perimeter of the unit engaging each of the thirteen hooks on the DAB housing through the thirteen windows in the walls of the trim cover receptacle.
5. After the DAB has been assembled, try pulling the trim cover and the airbag housing away from each other. This action will fully seat the edges of the windows into the cradles of the hooks and the vertical walls of the receptacle beneath the locating tabs (4) of the housing.
6. Before reinstalling the airbag onto the steering wheel, check that the blocking tab (1) in each of the trim cover (2) windows is oriented over the airbag housing hook (3) as shown.

7. Reinstall the DAB onto the steering wheel. (Refer to 10 - Restraints/AIR BAG, Driver - Installation) .

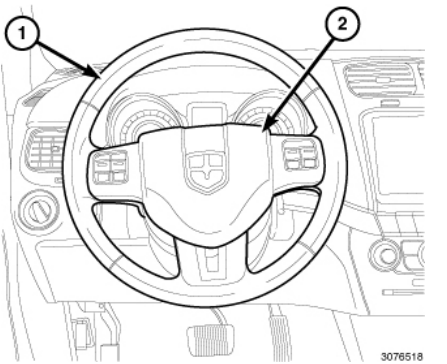


2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

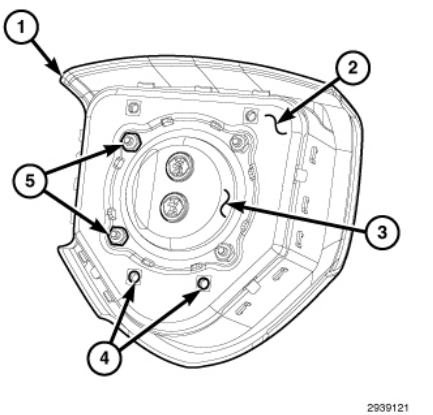
The injection molded, thermoplastic Driver AirBag (DAB) protective trim cover (2) is the most visible part of the DAB. The DAB is located in the center of the steering wheel (1), where it is secured with screws to the floating horn switch within the hub cavity of the three-spoke steering wheel. An injection molded, bright Dodge emblem is applied to the center of the trim cover.



Concealed beneath the DAB trim cover (1) are the folded airbag cushion, the airbag housing (2), the airbag inflator (3) and the retainers (5) that secure the inflator to the housing. The airbag cushion, housing and inflator are secured within an integral receptacle molded into the back of the trim cover. The vertical walls of this receptacle have numerous integral window features that are engaged by numerous hook features that are bent outward around the perimeter of the DAB housing. The DAB housing also has four well nuts (4) which are used to secure the floating horn switch to the back of the housing.

The DAB used in this vehicle is a multistage-type that complies with revised federal airbag standards to deploy with less force than those used in some prior vehicles. A radial deploying 67.3 centimeter (26.5 inch) diameter fabric airbag cushion with internal tethers is used. The airbag inflator is a dual-initiator, non-azide, pyrotechnic-type unit and is secured to the stamped metal airbag housing using four flanged hex nuts. Two keyed and color-coded connector receptacles on the DAB inflator connect the two inflator initiators to the vehicle electrical system through two jacketed, two-wire pigtail harnesses from the clockspring.

The DAB cannot be repaired, and must be replaced if deployed, ineffective or in any way damaged. The DAB trim cover and the floating horn switch are available for individual service replacement.



2014 Dodge JC - DODGE JOURNEY

INSTALLATION

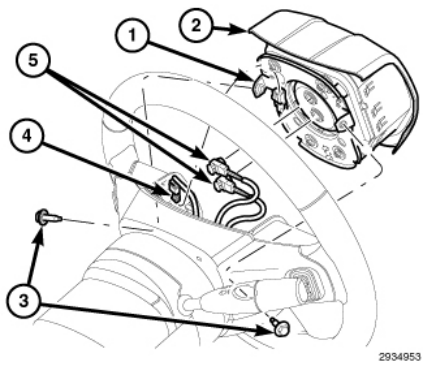
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the Driver AirBag (DAB), or becoming entrapped between the DAB cushion and the DAB trim cover. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

WARNING: **To avoid serious or fatal injury, the driver airbag trim cover must never be painted. Replacement airbags are serviced with trim covers in the original colors. Paint may change the way in which the material of the trim cover responds to an airbag deployment. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Driver AirBag (DAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the DAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the Driver AirBag (DAB) (2) and floating horn switch (1) unit close enough to the steering wheel to reconnect the electrical connections to the back of the airbag housing.
2. Reconnect the steering wheel wire harness connector (4) to the floating horn switch connector on the back of the switch.
3. Reconnect the wire connectors (5) to the airbag inflator connector receptacles by pressing straight in on the connector insulator. Be certain to engage each keyed and color-coded connector to the matching connector receptacle. You can be certain that each connector is fully engaged in its receptacle by listening carefully for a distinct, audible click as the connector latches snap into place.
4. Be certain to fully engage the plastic push-in retainer of the clockspring pigtail wires into the locator hole at the 12 o'clock position on the back of the floating horn switch.
5. Carefully position the DAB and floating horn switch unit into the steering wheel hub while tugging lightly upward on the clockspring pigtail wires for the airbag and tucking the wires into the upper hub cavity of the steering wheel. Be certain that none of the steering wheel wiring is pinched between the airbag housing or the horn switch and the steering wheel armature or, on vehicles equipped with a diesel engine, the steering wheel damper weight.
6. Working through the access holes in each side of the steering wheel rear trim cover, install and tighten the two screws (3) that secure the floating horn switch and DAB unit to the steering wheel armature. Tighten the screws to 13 N·m (10 ft. lbs.).
7. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The multistage Driver AirBag (DAB) is deployed by electrical signals generated by the Occupant Restraint Controller (ORC) through the DAB squib 1 and squib 2 circuits to the two initiators in the airbag inflator. By using two initiators, the airbag can be deployed at multiple levels of force. The force level is controlled by the ORC to suit the monitored impact conditions by providing one of several delay intervals between the electrical signals provided to the two initiators. The longer the delay between these signals, the less forcefully the airbag will deploy.

When the ORC sends the proper electrical signals to each initiator, the electrical energy generates enough heat to initiate a small pyrotechnic charge which, in turn ignites chemical pellets within the inflator. Once ignited, these chemical pellets burn rapidly and produce a large quantity of inert gas. The inflator is sealed to the back of the airbag housing and a diffuser in the inflator directs all of the inert gas into the airbag cushion, causing the cushion to inflate. As the cushion inflates, the DAB trim cover will split at predetermined breakout lines, then fold back out of the way. Following an airbag deployment, the airbag cushion quickly deflates by venting the inert gas towards the instrument panel through vent holes within the fabric used to construct the back (steering wheel side) panel of the airbag cushion.

Some of the chemicals used to create the inert gas may be considered hazardous while in their solid state before they are burned, but they are securely sealed within the airbag inflator. Typically, both initiators are used and all potentially hazardous chemicals are burned during an airbag deployment event. However, it is possible for only one initiator to be used during a deployment due to an airbag system fault; therefore, it is necessary to always confirm that both initiators have been used in order to avoid the improper disposal of potentially live pyrotechnic or hazardous materials. (Refer to 10 - Restraints - Standard Procedure) .

The inert gas that is produced when the chemicals are burned is harmless. However, a small amount of residue from the burned chemicals may cause some temporary discomfort if it contacts the skin, eyes, or breathing passages. If skin or eye irritation is noted, rinse the affected area with plenty of cool, clean water. If breathing passages are irritated, move to another area where there is plenty of clean, fresh air to breath. If the irritation is not alleviated by these actions, contact a physician.

The ORC monitors the condition of the DAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the DAB initiator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

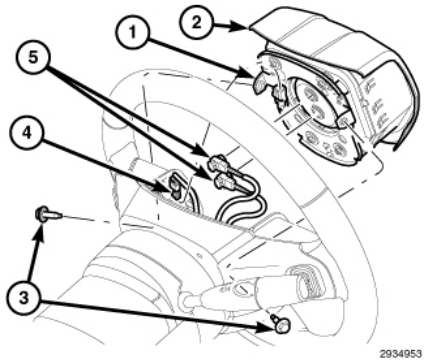
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag cushion and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

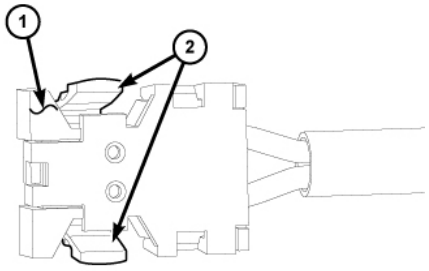
NOTE: The following procedure is for replacement of an ineffective or damaged Driver AirBag (DAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the DAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



2934953

1. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Working through the access holes in each side of the steering wheel rear trim cover, remove the two screws (3) that secure the floating horn switch (1) and Driver AirBag (DAB) (2) unit to the steering wheel armature.
3. Pull the DAB away from the steering wheel far enough to access and disengage the plastic push-in retainer of the clockspring pigtail wire harness from the locator hole at the 12 o'clock position on the back of the floating horn switch.
4. Pull the DAB and floating horn switch unit away from the steering wheel far enough to access the electrical connections (3 and 4) at the back of the airbag housing and switch unit.
5. Disconnect the steering wheel wire harness connector (4) from the floating horn switch connector on the back of the switch.

CAUTION: **Do not pull on the clockspring pigtail wires or pry on the connector insulators to disengage them from the Driver AirBag (DAB) inflator initiator connector receptacles. Improper removal of these pigtail wires and their connector insulators can result in damage to the airbag circuits or the connector insulators.**



2128307

6. The clockspring DAB pigtail wire connector insulators (1) are secured by integral latches (2) to the airbag inflator connector receptacles, which are located on the back of the DAB housing. Pinch both latches firmly, then pull the insulators straight out from the airbag inflator to disconnect them from the connector receptacles.
7. Remove the DAB from the steering wheel.

8. If the DAB has been deployed, the clockspring and the steering column must be replaced.

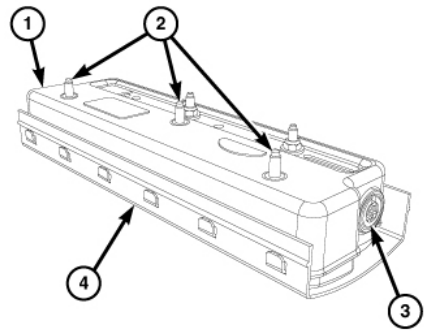
DESCRIPTION

A Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB) is used on vehicles manufactured for domestic markets. These airbags are passive, inflatable, Supplemental Restraint System (SRS) components. Vehicles with this equipment may be readily identified by the **SRS - AIRBAG** logo located on the upper outboard corner of the instrument panel steering column opening cover.

The KAB is concealed behind the steering column opening cover below the steering column on the driver side lower instrument panel. Located behind the steering column opening cover, the stamped metal airbag housing (1) is secured by three studs (2) with nuts to the stamped metal instrument panel lower reinforcement and mounting plate. A molded plastic protective cover (4) is secured over the folded airbag cushion by numerous hook formations stamped into the airbag housing that are engaged through window openings in the outer perimeter of the cover.

The airbag housing contains the airbag inflator and a heat shield. The airbag inflator is a single-initiator, non-azide hybrid-type unit that is secured to the housing by two studs with nuts and sealed within the airbag housing. The airbag is connected to the vehicle electrical system through a dedicated take out and connector insulator of the instrument panel wire harness that connects directly to the inflator initiator (3).



The KAB cannot be repaired, and must be replaced if deployed, ineffective or in any way damaged. If the airbag is deployed, the KAB and the steering column opening cover must be replaced.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the Inflatable Knee Blocker (IKB) airbag, or becoming entrapped between the IKB airbag cushion and the IKB cover. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the KAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .

1. Position the Knee AirBag (KAB) to the mounting plate on the instrument panel lower reinforcement.
2. Install and tighten the three nuts that secure the KAB studs to the mounting plate below the instrument panel. Tighten the nuts to 6 N·m (53 in. lbs.).
3. Reconnect the connector insulator of the instrument panel wire harness take out for the KAB to the inflator initiator connector receptacle by pressing straight in on the connector. You can be certain that the connector is fully engaged in its receptacle by listening carefully for a distinct, audible click as the connector latches snap into place.
4. Reinstall the steering column opening cover onto the instrument panel. (Refer to 23 - Body/Instrument Panel/COVER, Steering Column Opening - Installation) .
5. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

OPERATION

The Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB) is deployed by an electrical signal generated by the Occupant Restraint Controller (ORC) to which it is connected through a KAB line 1 (or squib) circuits to the initiator in the airbag inflator. The hybrid-type inflator assembly for the airbag contains a small canister of highly compressed inert gas. When the ORC sends the proper electrical signal to the airbag inflator, the electrical energy creates enough heat to ignite chemical pellets within the inflator.

Once ignited, these chemical pellets burn rapidly and produce the pressure necessary to rupture a containment disk in the inert gas canister. The inflator is sealed to the airbag cushion and a diffuser in the inflator directs all of the inert gas into the airbag cushion, causing the cushion to inflate. As the cushion inflates, the KAB protective cover will split at predetermined tear seam lines concealed on the underside of the cover, then fold open and out of the way.

The cushion protects the lower extremities of the vehicle operator and helps to keep the seat occupant properly positioned for the Driver AirBag (DAB) deployment during a frontal impact collision. Following an airbag deployment, the KAB cushion quickly deflates by venting the inert gas through the loose weave of the fabric used to construct the instrument panel side of the airbag cushion, and the deflated cushion hangs down loosely from the lower instrument panel.

The ORC monitors the condition of the KAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the KAB initiator and squib circuit requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

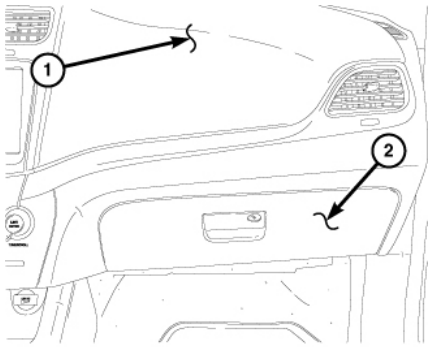
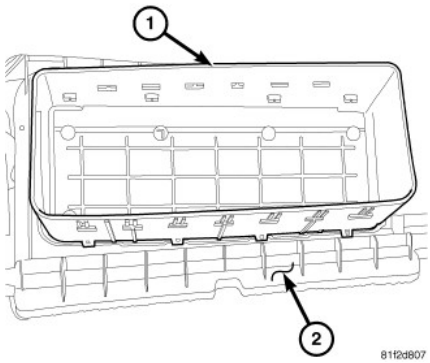
DESCRIPTION

The horizontal surface of the instrument panel top pad (1) above the glove box (2) is the most visible part of the Passenger AirBag (PAB). The PAB door is integral to the top of the instrument panel top pad forward of and above the glove box on the instrument panel in front of the front seat passenger seating position.

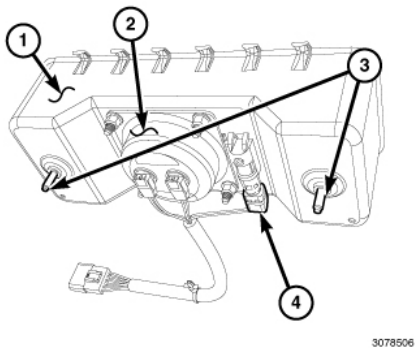


Located below the PAB door area of the instrument panel top pad (2), the molded thermoplastic PAB retainer or chute (1) is secured to the underside of the top pad. The retainer defines the airbag door breakout area of the top pad and serves as the receptacle for the PAB cushion and housing. Numerous small window openings on the forward and rearward flanges of the receptacle receive mating hook formations stamped into the airbag housing, which locate and secure the housing to the top pad.



The PAB unit (1) is also secured by two studs (3) and nuts to a bracket integral to the instrument panel structural support. The PAB unit used in this vehicle is a multistage type that complies with revised federal airbag standards to deploy with less force than those used in some prior vehicles. The PAB unit consists of a stamped metal housing, the airbag cushion, and the airbag inflator (2). The airbag inflator is secured to the housing by four screws and nuts. The airbag housing contains the folded airbag cushion. An approximately 66 centimeter (26 inch) wide by 76 centimeter (30 inch) high rectangular fabric cushion is used.

The airbag inflator is a non-azide, pyrotechnic-type unit that is secured to and sealed within the airbag housing. Two dedicated take outs and yellow connectors of the instrument panel wire harness with keyed, color-coded (black and orange) insulators connect the two inflator initiators to the vehicle electrical system. Vehicles manufactured for domestic markets also include an active vent tether cutter (4) that is connected through a third dedicated take out and connector of the instrument panel wire harness.



The PAB cannot be repaired, and must be replaced if deployed, ineffective, or in any way damaged. The PAB door and retainer are serviced only as a unit with the instrument panel top pad. If the PAB is deployed, the instrument panel top pad must also be replaced.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

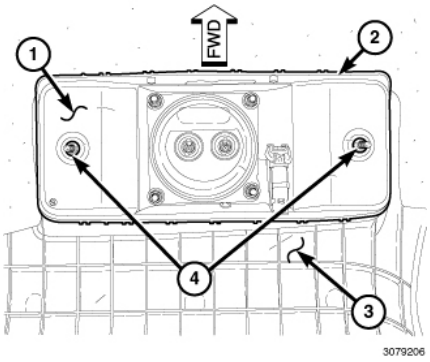
WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the passenger airbag, or becoming entrapped between the passenger airbag cushion and the instrument panel top pad. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

WARNING: **To avoid serious or fatal injury, the instrument panel top pad must never be painted. Replacement top pads are serviced in the original colors. Paint may change the way in which the material of the top pad responds to an airbag deployment. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Passenger AirBag (PAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the PAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Place the instrument panel top pad (3) on a suitable work surface with the Passenger AirBag (PAB) retainer or chute (2) receptacle facing up. Be certain to take the proper precautions to prevent the top pad from receiving cosmetic damage during the following procedures.
2. Carefully position the PAB housing to the PAB retainer or chute receptacle. The side of the housing with 6 hooks faces the defroster duct outlet or forward in the vehicle.
3. Engage all of the hooks on one side of the PAB housing through the windows on the same side of the PAB retainer or chute, then rotate the opposite side of the PAB housing downward into the receptacle.
4. Inspect around the perimeter of the PAB making certain each of the hooks on the PAB housing is fully engaged through the windows in the forward and rearward vertical walls of the PAB retainer or chute receptacle.
5. Reinstall the top pad onto the instrument panel. (Refer to 23 - Body/Instrument Panel/PAD, Instrument Panel - Installation) .
6. Be certain to tighten the nuts that secure the studs (4) of the PAB to the bracket on the instrument panel structural support. Tighten the nuts to 8 N·m (71 in. lbs.).
7. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The multistage Passenger AirBag (PAB) is deployed by electrical signals generated by the Occupant Restraint Controller (ORC) through the PAB squib 1 and squib 2 circuits to the two initiators in the airbag inflator. By using two initiators, the PAB can be deployed at multiple levels of force. The force level is controlled by the ORC to suit the monitored impact conditions by providing one of multiple delay intervals between the electrical signals provided to the two initiators. The longer the delay between these signals, the less forcefully the airbag will deploy.

When the ORC sends the proper electrical signals to each initiator, the electrical energy generates enough heat to initiate a small pyrotechnic charge which, in turn ignites chemical pellets within the inflator. Once ignited, these chemical pellets burn rapidly and produce a large quantity of inert gas. The inflator is sealed to the airbag cushion and a diffuser in the inflator directs all of the inert gas into the airbag cushion, causing the cushion to inflate. As the cushion inflates, the PAB door will split at predetermined tear seam lines concealed on the inside surface of the door, then the door will pivot up over the top of the instrument panel and out of the way. Following an airbag deployment, the airbag cushion quickly deflates by venting the inert gas through a discrete vent hole in each fabric side panel of the airbag cushion.

Domestic market vehicles are equipped with an active vent tether cutter unit. The ORC monitors a seat track position sensor on the passenger front seat. If the seat is in the full forward position when an airbag deployment occurs, the ORC signals the tether cutter to cut the tether that normally keeps active vent flaps in the airbag cushion closed. With the tether cut, the active vents open to reduce airbag deployment force and reduce the possibility of an airbag-induced injury when the passenger is seated close to the deploying airbag. If the passenger front seat is not in the full forward position, the tether is not cut and the active vents in the cushion remain closed during deployment.

Typically, both initiators are used during a PAB deployment event. However, it is possible for only one initiator to be used during a deployment due to an airbag system fault and, it is also possible that the tether cutter was not used during a deployment. It is necessary to always confirm that both initiators and the tether cutter have been used in order to avoid the improper disposal of potentially live pyrotechnic materials. (Refer to 10 - Restraints - Standard Procedure) .

The ORC monitors the condition of the PAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the PAB inflator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

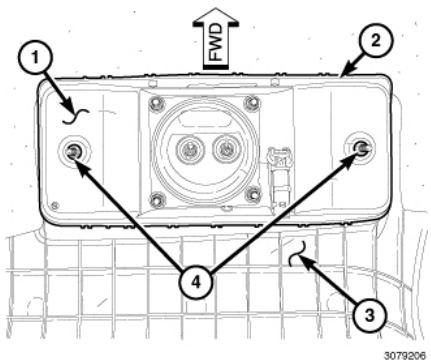
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

NOTE: The following procedure is for replacement of an ineffective or damaged Passenger AirBag (PAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the PAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Remove the top pad (3) and Passenger AirBag (PAB) from the instrument panel as a unit. (Refer to 23 - Body/Instrument Panel/PAD, Instrument Panel - Removal) .
3. Place the top pad on a suitable work surface with the top facing down. If the top pad will be reused, be certain to take the proper precautions to prevent the top pad from receiving cosmetic damage during the following procedures.
4. Disengage each of the hooks on one side of the PAB housing (1) from the windows in the forward and rearward vertical walls of the PAB retainer or chute (2) on the underside of the top pad. To disengage the hooks, use hand pressure to pull the adjacent edge of the PAB housing firmly and evenly upward out of the retainer receptacle, while at the same time pulling the upper edge of the receptacle wall outward far enough to disengage the hooks.
5. With all of the hooks on one side of the PAB housing disengaged from the retainer, rotate that side of the housing upward far enough to disengage the hooks on the opposite side of the housing from the retainer.
6. With all of the hooks disengaged, lift the PAB housing, inflator, and cushion as a unit from the receptacle of the PAB retainer or chute on the underside of the instrument panel top pad.

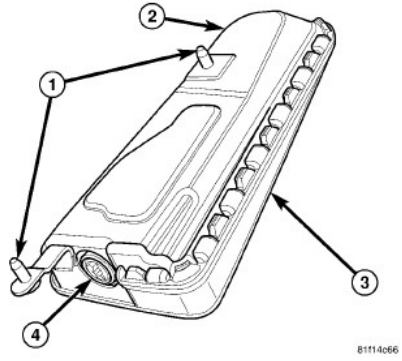
DESCRIPTION

The Seat AirBags (SAB) (also known as pelvic and thoracic airbags) are standard equipment in all markets except Mexico. Vehicles with this equipment can be readily identified by a sewn tag with the **SRS - AIRBAG** logo located on the outboard side of the front seat back trim cover. These airbags are completely concealed beneath the seat back trim cover on the upper outboard sides of both front seat backs. Each SAB unit is inserted into a sewn pouch called an intensifier on the inside of the trim cover, then secured to the seat back frame by nuts on two studs (1). Both studs are installed on a stamped metal bracket. The stud on one end of the bracket exits through the SAB housing (2), while the second stud is located on the opposite end of the bracket that extends from the lower end of the housing.

The folded SAB cushion is contained within and protected by a molded plastic cover (3) secured to the outer edges of the housing. The SAB cushion is constructed of a coated nylon fabric.



The SAB housing contains the airbag inflator and a heat shield. The inflator is a single-initiator, pyrotechnic-type unit that is secured to and sealed within the SAB housing. The SAB is connected to the vehicle electrical system through a dedicated jumper wire harness with a connector insulator that connects directly to the inflator initiator (4). The connector insulators are uniquely keyed and color-coded to ensure they can only be connected to the initiator.

The SAB cannot be repaired, and must be replaced if deployed, ineffective, or in any way damaged. If the SAB is deployed, the seat back frame, the seat back foam cushion, the seat back trim cover and the seat airbag jumper wire harness must also be replaced.

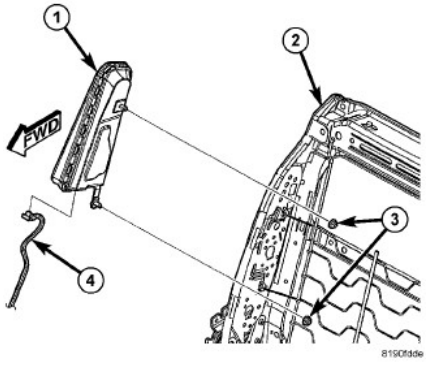
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Seat AirBag (SAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the SAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



CAUTION: **The seat airbag (1) must be installed into the nylon mesh pouch integral to the front seat back trim cover before the airbag or the trim cover are installed on the front seat back frame (2). Failure to do so will adversely affect the function of the seat airbag system.**

1. Carefully slide the Seat AirBag (SAB) into the nylon pouch (intensifier) integral to the outboard side of the front seat back trim cover and engage the two SAB studs through the holes provided in the pouch. Be certain not to tear or damage the nylon pouch or the trim cover.
2. Position the SAB and trim cover as a unit to the outboard side of the seat back frame and insert the studs through the mounting holes in the frame.
3. Install and tighten the two nuts (3) that secure the SAB to the outboard side of the seat back frame. Tighten the nuts to 10 N·m (88 in. lbs.).
4. Reconnect the seat jumper wire harness (4) connector to the SAB inflator. Be certain that the connector latches and lock are fully engaged.

   CAUTION: **Be certain that all of the trim is properly reinstalled on the front seat back frame. Failure to do so will adversely affect the function of the seat airbag system.**

5. Reinstall the trim onto the front and back of the front seat back frame. (Refer to 23 - Body/Seats/COVER, Seat Back - Installation) .
6. Reinstall the front seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .
7. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

OPERATION

Each Seat AirBag (SAB) (also known as a pelvic and thoracic airbag) is deployed individually by an electrical signal generated by the Occupant Restraint Controller (ORC) to which it is connected through left or right SAB line 1 and line 2 (or squib) circuits. The hybrid-type inflator assembly for each SAB contains a small canister of highly compressed inert gas. When the ORC sends the proper electrical signal to the SAB inflator, the electrical energy creates enough heat to ignite chemical pellets within the inflator.

Once ignited, these chemicals burn rapidly and produce the pressure necessary to rupture a containment disk in the inert gas canister. The inflator and inert gas canister are sealed and connected so that all of the released gas is directed into the folded SAB cushion, causing the cushion to inflate. As the cushion inflates it will split the retainer wrap, the sewn pouch (intensifier) and the outboard side of the seat back trim cover and expand into the area between the outboard side of the front seat and the front door to form a cushion to protect the front seat occupant during a side impact collision or a vehicle rollover incident.

Following the SAB deployment, the SAB cushion slowly deflates by venting the inert gas through the loose weave of the cushion fabric, and the deflated cushion hangs down loosely from the outboard side of the front seat back.

The ORC monitors the condition of the SAB through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the SAB inflator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

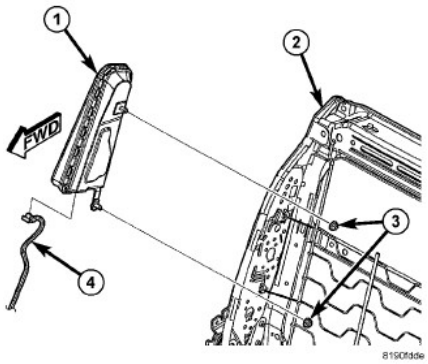
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

NOTE: The following procedure is for replacement of an ineffective or damaged Seat AirBag (SAB). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the SAB has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the front seat to its most forward position for easiest access to the front seat mounting hardware.
2. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
3. Remove the front seat from the vehicle. (Refer to 23 - Body/Seats/SEAT - Removal) .

   CAUTION: **During removal of the seat back trim cover, be certain not to tear or damage the integral nylon pouch that contains the seat airbag. If the nylon pouch or the trim cover are torn or damaged, the entire front seat back trim cover must be replaced with a new unit.**

4. Remove the trim from the front and back of the front seat back frame (2), but do not remove from the outboard side of the seat back trim cover until after the Seat AirBag (SAB) has been detached from the seat. (Refer to 23 - Body/Seats/COVER, Seat Back - Removal) .

   CAUTION: **Do not pull on the seat airbag jumper wire harness (4) take out or pry on the connector insulator to disengage the connector from the seat airbag (1) inflator connector receptacle. Improper removal of this take out and its connector insulator can result in damage to the airbag circuits or the connector insulator.**

5. Disconnect the SAB jumper wire harness connector from the SAB inflator. Slide the yellow locking tab down, then squeeze the two latch tabs on the connector insulator. Pull the insulator straight out from the inflator to disconnect it from the connector receptacle.
6. Remove the two nuts (3) that secure the SAB to the side of the seat back frame.
7. Grasp the outboard side of the seat back trim cover and pull the trim cover and cushion over the top of the seat back frame. This will allow room to remove the SAB without damaging the trim cover or the cushion.
8. Working between the seat back trim cover and the seat back frame, carefully disengage the two SAB studs from the nylon pouch (intensifier and slide the SAB

out of the pouch. Be certain not to tear or damage the nylon pouch or the trim cover.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

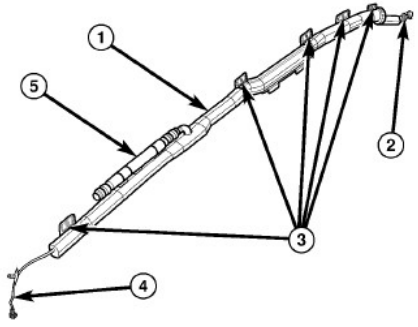
DESCRIPTION

Side curtain airbags (also known as Side AirBag Inflatable Curtains/SABIC) are standard factory installed equipment in this vehicle for all markets except Mexico. These airbags are passive, inflatable, Supplemental Restraint System (SRS) components, and vehicles with this equipment can be readily identified by a molded identification trim button with the **SRS - AIRBAG** logo located near the top of each upper B-pillar and C-pillar trim. This system is designed to reduce injuries to the vehicle occupants in the event of a side impact collision or a vehicle rollover incident.

8098029e

Vehicles equipped with side curtain airbags have two individually controlled curtain airbag units (1). These airbag units are concealed and mounted above the headliner where they are each secured to one of the roof side rails. Each folded airbag cushion is contained within a fabric wrap that extends along the roof rail from the A-pillar at the front of the vehicle to near the D-pillar (5 passenger seating) or to the liftgate opening header (7 passenger seating) at the rear of the vehicle.

Two plastic retainer clips secure a long tether (2) to the inside of the A-pillar downward from the front of the airbag cushion, where it is retained to a slot in the base of the A-pillar near the belt line with a metal hook followed by a plastic push-in retainer to secure the hook in the slot. On vehicles with 5 passenger seating, a retainer clip on another short tether (4) at the rear of the cushion is secured by a screw to the upper liftgate opening header inner reinforcement. On vehicles with 7 passenger seating, the rear of the cushion turns inboard at the D-pillar and is secured by nuts to a weld stud on the upper liftgate opening header inner reinforcement.



81101e30

The hybrid-type inflator (5) for each airbag is secured to the airbag unit above the C-pillar. A stamped metal bracket on the inflator is secured by two screws to the inner roof rail above the C-pillar. The inflator is connected to the airbag cushion by a tubular manifold. The entire cushion and inflator assembly is temporarily secured through plastic mounting tabs (3) with plastic push-in retainers, then is permanently secured by a combination of screws and nuts to weld studs spaced along the inside of the roof rail.

A take out and connector of the body wire harness is routed up each C-pillar to the roof rail to the connector receptacle of the initiator at the rear of the airbag inflator. This connects the airbag unit to the Occupant Restraint Controller (ORC).

The side curtain airbag unit cannot be adjusted or repaired and must be replaced if deployed, ineffective, or in any way damaged. Once a side curtain airbag has been deployed, the complete airbag unit, the headliner, the upper A, B, C and D-pillar trim, and all other visibly damaged components must be replaced.

INSTALLATION

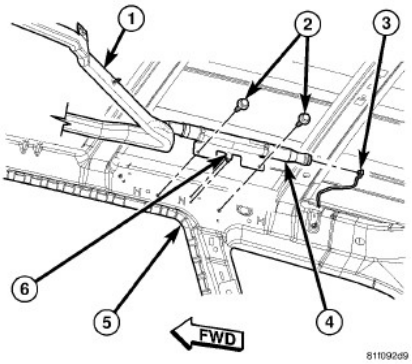
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

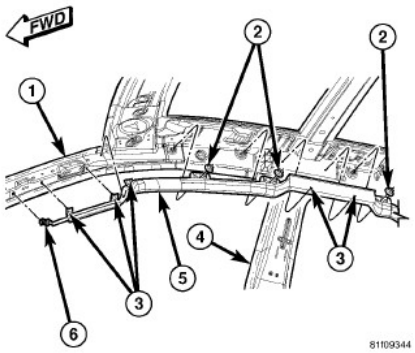
WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the side curtain airbag, or becoming entrapped between the side curtain airbag cushion and the headliner. Failure to observe this warning could result in occupant injuries upon airbag deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the side curtain airbag has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the side curtain airbag (1) and inflator (4) into the vehicle as a unit.
2. Position the inflator mounting bracket to the inner roof rail above the C-pillar (5) and engage the locating tab of the mounting bracket with the locating hole in the roof side rail.
3. Engage the plastic push-in retainer (6) that temporarily secures the inflator mounting bracket to the inner roof rail.
4. Install and tighten the two screws (2) that secure the inflator mounting bracket to the inner roof rail. Tighten the screws to 9 N·m (80 in. lbs.).
5. Reconnect the body wire harness connector (3) to the connector receptacle at the rear of the inflator (2). Be certain to route the wiring outboard of the inflator, between the inflator and the roof side rail.
6. Working from the inflator toward the front of the vehicle, engage the three mounting tabs of the side curtain airbag (5) over the weld studs on the inner roof rail above the rear and front door openings.
7. Working from the inflator toward the front of the vehicle, engage the plastic push-in retainers (3) that temporarily secure the side curtain airbag and the front tether to the inner roof rail over the B-pillar (4) and the inner A-pillar (1).
8. Install and tighten the three nuts (2) that secure the side curtain airbag mounting tabs to the weld studs on the inner roof rail above the front and rear door openings. Tighten the nuts to 9 N·m (80 in. lbs.).
9. Engage the metal hook (6) that secures the front tether to the inner A-pillar near the belt line.

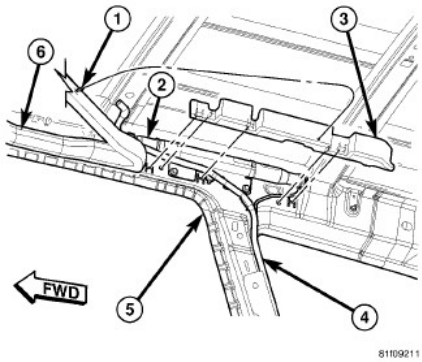
10. Engage the plastic clip that secures the front tether hook to the inner A-pillar. Both the hook and the plastic clip are secured in the same slotted hole of the A-pillar, but the hook MUST be installed prior to the clip.

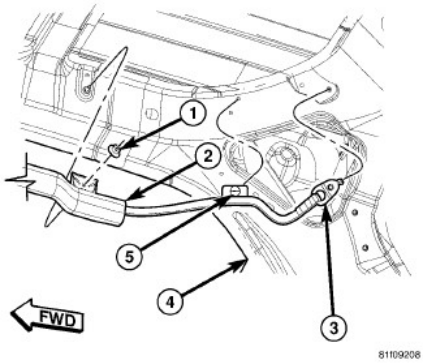


11. Position the Head Impact Countermeasure (HIC) rib cartridge (3) over the airbag inflator (2) above the C-pillar (5) and align the front and rear locating bosses of the cartridge with the slots of the inner roof rail. Be certain the wiring and, if equipped, the sunroof drain hose (4) are routed through the clearance notch at the bottom of the cartridge, between the cartridge and the roof rail.

12. Using hand pressure, press the HIC rib cartridge toward the inner roof rail until the three snap clip retainers snap into place. Be certain the snap clips are fully engaged with the slots in the roof rail.

13. Engage the plastic push-in retainer (1) that secures the side curtain airbag (6) to the HIC rib cartridge.





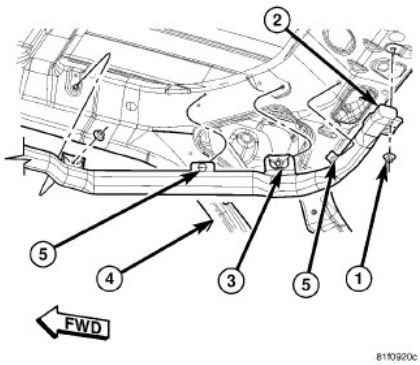
Side Airbag Rear - 5 Passenger Seating

14. Working from the inflator toward the rear of the vehicle, engage the mounting tabs of the side curtain airbag (2) to the weld studs on the inner roof rail above the quarter window opening and, if equipped with seven passenger seating, the upper liftgate opening inner reinforcement.

15. Engage the plastic push-in retainers (5) that temporarily secure the airbag or rear tether mounting tabs to the inner roof rail above the D-pillar (4).

16. Install and tighten the nut (1) that secures the side curtain airbag mounting tab to the weld stud on the inner roof rail above the quarter window opening.

17. On vehicles with 5 passenger seating, install and tighten the screw that secures the rear tether retainer clip (3) to the inner roof rail above the D-pillar (4). Be certain the anti-rotation tab of the retainer clip is engaged in the clearance hole of the roof rail. Tighten the screw to 9



N·m (80 in. lbs.).

Side Airbag Rear - 7 Passenger Seating

18. On vehicles with 7 passenger seating, install and tighten the screw (3) that secures the side curtain airbag mounting tab to the inner roof rail above the D-pillar. Tighten the screw to 9 N·m (80 in. lbs.).

19. On vehicles with 7 passenger seating, install and tighten the nut that secures the side curtain airbag rear mounting tab to the weld stud on the upper liftgate opening inner reinforcement. Tighten the nut to 9 N·m (80 in. lbs.).

20. Reinstall the headliner into the vehicle. (Refer to 23 - Body/Interior/HEADLINER - Installation) .

21. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

OPERATION

Each side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC) is deployed individually by an electrical signal generated by the Occupant Restraint Controller (ORC) to which it is connected through left or right curtain airbag line 1 and line 2 (or squib) circuits. The hybrid-type inflator assembly for each airbag contains a small canister of highly compressed inert gas. When the ORC sends the proper electrical signal to the airbag inflator, the electrical energy creates enough heat to ignite chemical pellets within the inflator.

Once ignited, these chemicals burn rapidly and produce the pressure necessary to rupture a containment disk in the inert gas canister. The inflator and inert gas canister are sealed and connected to a tubular manifold so that all of the released gas is directed into the folded curtain airbag cushion, causing the cushion to inflate. As the airbag cushion inflates it will drop down from the roof rail between the edge of the headliner and the side glass/body pillars to form a curtain-like cushion to protect the vehicle occupants during a side impact collision or a vehicle rollover incident.

The front and rear tethers keep the side airbag cushion taut to the side of the vehicle, while ramps integral to the airbag unit and the adjacent interior trim components direct the inflating cushion downward, ensuring that the airbag will deploy in the proper position. Following the airbag deployment, the airbag cushion slowly deflates by venting the inert gas through the loose weave of the cushion fabric, and the deflated cushion hangs down loosely from the roof rail.

The ORC monitors the condition of the side curtain airbags through circuit resistance, and will illuminate the airbag indicator in the instrument cluster and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the side curtain airbag inflator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

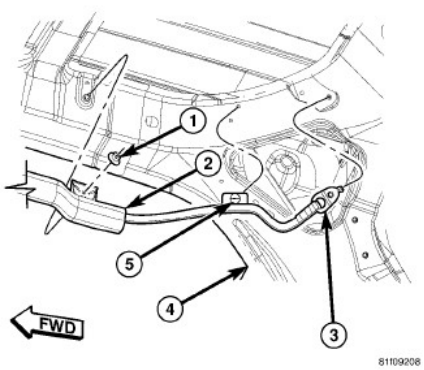
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

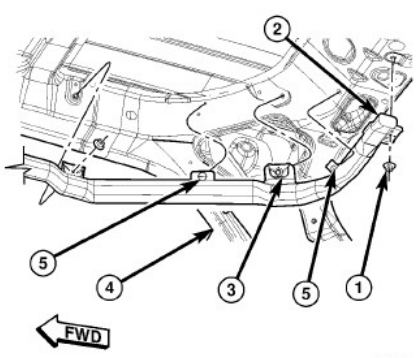
WARNING: **To avoid serious or fatal injury when removing a deployed airbag, rubber gloves, eye protection, and a long-sleeved shirt should be worn. There may be deposits on the airbag unit and other interior surfaces. In large doses, these deposits may cause irritation to the skin and eyes.**

WARNING: **To avoid serious or fatal injury, use extreme care to prevent any foreign material from entering the side curtain airbag, or becoming entrapped between the side curtain airbag cushion and the headliner. Failure to observe this warning could result in occupant injuries upon airbag deployment.**



Side Airbag Rear - 5 Passenger Seating

NOTE: The following procedure is for replacement of an ineffective or damaged side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC). If the airbag is ineffective or damaged, but not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the side curtain airbag has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the airbag from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



Side Airbag Rear - 7 Passenger Seating

1. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Remove the headliner from the vehicle. (Refer to 23 - Body/Interior/HEADLINER - Removal) .
3. On vehicles with 5 passenger seating, remove the screw that secures the side curtain airbag (2) rear tether retainer clip (3) to the inner roof rail above the D-pillar (4).

4. On vehicles with 7 passenger seating, remove the nut (1) that secures the side curtain airbag (2) rear mounting tab to the weld stud on the upper liftgate opening inner reinforcement.

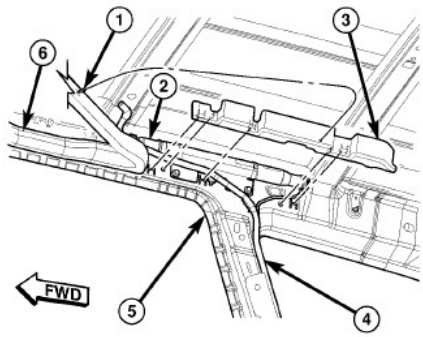
5. On vehicles with 7 passenger seating, remove the screw (3) that secures the side curtain airbag mounting tab to the inner roof rail above the D-pillar (4).

6. Remove the nut (1) that secures the side curtain airbag mounting tab to the weld stud on the inner roof rail above the quarter window opening.

7. Disengage the plastic push-in retainers (5) that secure the airbag or rear tether mounting tabs to the inner roof rail above the D-pillar.

8. Disengage the plastic push-in retainer (1) that secures the side curtain airbag (6) to the Head Impact Countermeasure (HIC) rib cartridge (3) covering the airbag inflator (2) on the inner roof rail above the C-pillar (5).

9. Using a trim stick or another suitable wide flat-bladed tool, carefully pry the HIC rib cartridge away from the inner roof rail far enough to disengage the three snap clip retainers and remove the cartridge from the roof rail. Be certain not to damage the wiring or, if equipped, the sunroof drain hose (4) routed between the cartridge and the roof rail.



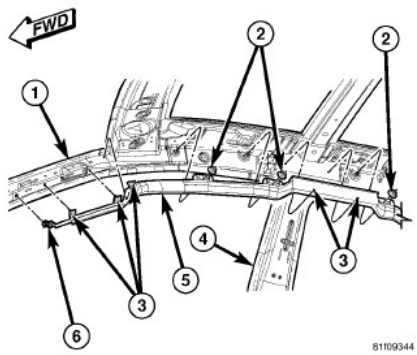
81109211

10. Disengage the plastic clip that secures the side curtain airbag (5) front tether hook (6) to the inner A-pillar (1) near the belt line.

11. Disengage the metal hook that secures the front tether to the inner A-pillar. Both the hook and the plastic clip are secured in the same slotted hole of the A-pillar.

12. Remove the three nuts (2) that secure the side curtain airbag mounting tabs to the weld studs on the inner roof rail above the front and rear door openings.

13. Disengage the plastic push-in retainers (3) that secure the side curtain airbag and the front tether to the inner A-pillar and the inner roof rail over the B-pillar (4).



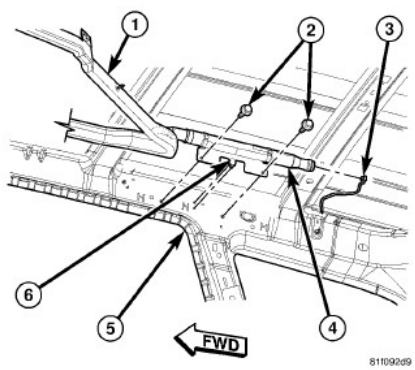
81109344

14. Disconnect the body wire harness connector (3) from the connector receptacle at the rear of the side curtain airbag inflator (4) located on the inner roof rail above the C-pillar (5).

15. Remove the two screws (2) that secure the inflator mounting bracket to the inner roof rail.

16. Disengage the plastic push-in retainer (6) that secures the inflator mounting bracket to the inner roof rail.

17. Remove the side curtain airbag (1) and inflator from the vehicle as a unit.



811092d9

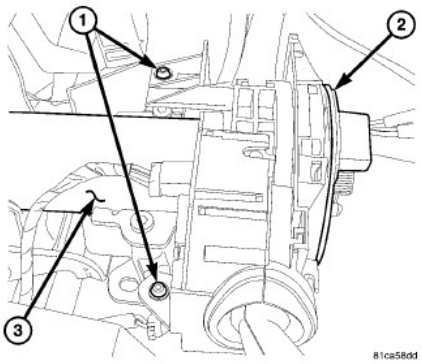
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **If the clockspring is not properly centered in relation to the Steering Angle Sensor (SAS), steering wheel, steering shaft and steering gear, it may be damaged or Diagnostic Trouble Codes (DTC) may be set in the SAS. . Service replacement clocksprings are shipped pre-centered and with a locking pin installed. This locking pin should not be removed until the clockspring has been installed on the steering column.**



1. Reinstall the multi-function switch onto the clockspring. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/SWITCH, Multifunction - Installation) .
2. With the centered clockspring rotor and case secured to each other, or with the plastic locking pin installed, carefully slide the clockspring down over the steering column upper shaft far enough to access and reconnect the following instrument panel wire harness connectors and their wiring retainers to the clockspring, as the vehicle is equipped:
   a. Multi-function switch connector
   b. Steering Angle Sensor (SAS) connector
   c. Two clockspring connectors
   d. Adjustable pedal switch connector, if the vehicle is so equipped.
3. Position the clockspring (2) onto the steering column housing (3).
4. From above the steering column, install and tighten the two captive screws (1) that secure the back of the clockspring to the steering column. Tighten the screws to 3 N·m (25 in. lbs.).
5. Install and tighten the screw (2) on the face of the clockspring that secures the clockspring (1) to the steering column. Tighten the screw to 3 N·m (25 in. lbs.).
6. Reinstall the upper and lower shrouds onto the steering column housing. (Refer to 19 - Steering/Column/SHROUD, Steering Column - Installation) .
7. Reinstall the steering wheel onto the steering column. (Refer to 19 - Steering/Column/WHEEL, Steering - Installation) .

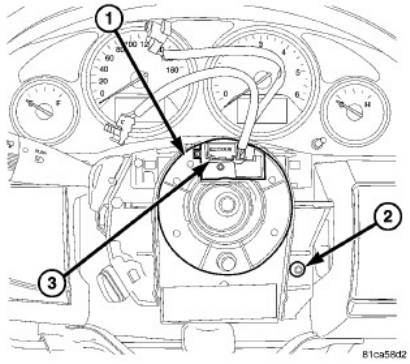
NOTE: When reinstalling the steering wheel, be certain to index the engagement dowel/drive pin on the upper surface of the clockspring rotor with the slot cast into the lower surface of the steering wheel armature hub.

8. Remove the plastic locking pin or any other device that is being used to secure the clockspring rotor to the clockspring case to maintain clockspring centering.

9. Reconnect the steering wheel wire harness connector to the upper clockspring connector receptacle. Be certain that the steering wheel wire harness is routed between the steering wheel back trim cover and the steering wheel armature.

10. Reinstall the Driver AirBag (DAB) onto the steering wheel. (Refer to 10 - Restraints/AIR BAG, Driver - Installation) .

11. Reconnect the negative cable to the battery.



NOTE:

Proper clockspring installation must also be confirmed by viewing the SAS Menu Item, Data Display function using a diagnostic scan tool.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The clockspring is a mechanical electrical circuit component that is used to provide continuous electrical continuity between the fixed instrument panel wire harness and the electrical components mounted on or in the rotating steering wheel. On this vehicle the rotating electrical components include the Driver AirBag (DAB), the horn switch, the speed control switch, the remote radio switches and the Electronic Vehicle Information Center (EVIC) control switches, if the vehicle is so equipped. The clockspring case is positioned and secured near the top of the steering column. The fixed connector receptacles on the back of the fixed clockspring case connect the clockspring to the vehicle electrical system through take outs with connectors from the instrument panel wire harness.

The turn signal cancel cam is integral to the rim of the clockspring rotor hub within the clockspring case so it also moves with the rotation of the steering wheel. Two short pigtail wires on the upper surface of the clockspring rotor connect the clockspring to the DAB, while a steering wheel wire harness connected to the connector receptacle on the upper surface of the clockspring rotor completes circuits to the horn switch, the speed control switch and, if the vehicle is so equipped, to the optional remote radio switches and EVIC control switch on the steering wheel. Another connector receptacle is dedicated to the inputs and outputs of the Local Interface Network (LIN) data bus master node and Controller Area Network (CAN) data bus gateway integral to the Steering Angle Sensor (SAS) on the back of the clockspring case.

The clockspring tape has travel limits and will be damaged by being wound too tightly during full stop-to-stop steering wheel rotation. To prevent this from occurring, the clockspring is centered when it is installed on the steering column. Centering the clockspring indexes the clockspring tape and the SAS integral to the clockspring to the movable steering components so that the tape can operate within its designed travel limits and the SAS can accurately monitor and communicate steering wheel inputs. However, if the clockspring is removed from the steering column or if the steering shaft is disconnected from the steering gear, the clockspring spool and the SAS can change position relative to the movable steering components and relative to each other. The clockspring must be replaced if proper centering has been compromised or the tape may be damaged and Diagnostic Trouble Codes (DTC) or faults may be set within the SAS.

Service replacement clocksprings are shipped pre-centered and with a plastic locking pin installed. This locking pin should not be removed until the clockspring and the steering wheel have been installed on the steering column. If the locking pin is removed before the clockspring is properly installed, the clockspring must be replaced with a new unit. Proper clockspring installation must also be confirmed by viewing the SAS Menu Item, Data Display function using a diagnostic scan tool.

The hard wired clockspring circuits as well as the hard wired input and output circuits of the SAS may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the SAS or the electronic controls and communication between the SAS and other modules and devices. The most reliable, efficient and accurate means to diagnose the SAS or the electronic controls and communication related to clockspring or SAS operation requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

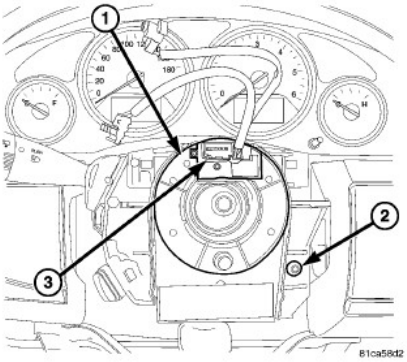
REMOVAL

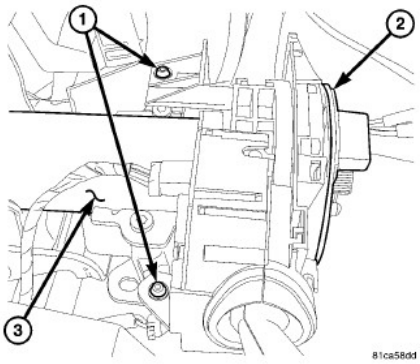
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **Always turn the steering wheel until the front wheels are in the straight-ahead position. Then, prior to removing the clockspring from the steering column or disconnecting the steering column from the steering gear, lock the steering wheel to the steering column or securely fasten the clockspring rotor to the clockspring case. If clockspring centering has been compromised for ANY reason, the entire clockspring and Steering Angle Sensor (SAS) unit MUST be replaced with a new unit.**



1. Place the front wheels in the straight ahead position.
2. Disconnect and isolate the negative cable from the battery.
3. Remove the Driver AirBag (DAB) from the steering wheel. (Refer to 10 - Restraints/AIR BAG, Driver - Removal) .
4. Disconnect the steering wheel wire harness connector from the upper clockspring connector receptacle (3).
5. Remove the steering wheel from the steering column. (Refer to 19 - Steering/Column/WHEEL, Steering - Removal) .
6. If the removed clockspring (1) is to be reused, be certain to secure the clockspring rotor to the clockspring case to maintain clockspring centering until the steering wheel is reinstalled on the steering column. If clockspring centering is not maintained, the clockspring and Steering Angle Sensor (SAS) unit must be replaced with a new unit. (Refer to 10 - Restraints/CLOCKSPRING - Standard Procedure) .
7. Remove the upper and lower shrouds from the steering column. (Refer to 19 - Steering/Column/SHROUD, Steering Column - Removal) .
8. Remove the screw (2) from the face of the clockspring that secures the clockspring to the steering column.
9. From above the steering column (3), fully loosen the two captive screws (1) that secure the back of the clockspring (2) to the steering column housing. These screws are captive and will remain with the clockspring after it is removed from the steering column.



10. Pull the clockspring rearward away from the top of the steering column far enough to access and disconnect the following instrument panel wire harness connectors and their wiring retainers from the clockspring, as the vehicle is equipped:
    a. Multi-function switch connector
    b. Steering Angle Sensor (SAS) connector

c. Two clockspring connectors

d. Adjustable pedal switch connector, if the vehicle is so equipped.

11. Remove the clockspring from the steering column. The clockspring cannot be repaired. It must be replaced if ineffective, damaged, centering has been compromised or the DAB has been deployed.

12. Remove the multi-function switch from the clockspring. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/SWITCH, Multifunction - Removal) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

STANDARD PROCEDURE - CLOCKSPRING CENTERING

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **Always turn the steering wheel until the front wheels are in the straight-ahead position. Then, prior to removing the clockspring from the steering column or disconnecting the steering column from the steering gear, lock the steering wheel to the steering column or securely fasten the clockspring rotor to the clockspring case. If clockspring centering has been compromised for ANY reason, the entire clockspring and Steering Angle Sensor (SAS) unit MUST be replaced with a new unit.**

Like the clockspring in a timepiece, the clockspring tape has travel limits and can be damaged by being wound too tightly during full stop-to-stop steering wheel rotation. To prevent this from occurring, the clockspring is centered when it is installed on the steering column. Centering the clockspring indexes the clockspring tape and the SAS integral to the clockspring to the movable steering components so that the tape can operate within its designed travel limits and the SAS can accurately monitor and communicate steering wheel inputs.

However, if the clockspring is removed from the steering column or if the steering shaft is disconnected from the steering gear, the clockspring spool and the SAS can change position relative to the movable steering components and relative to each other. The clockspring must be replaced if proper centering has been compromised or the tape may be damaged and Diagnostic Trouble Codes (DTC) or faults may be set within the SAS.

Service replacement clocksprings are shipped pre-centered and with a plastic locking pin installed. This locking pin should not be removed until the clockspring and the steering wheel have been installed on the steering column. If the locking pin is removed before the clockspring is installed on a steering column, the clockspring and SAS must be replaced with a new unit. Proper clockspring installation must also be confirmed by viewing the SAS Menu Item, Data Display function using a diagnostic scan tool.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

ACTIVE RESTRAINTS

The active restraints for this vehicle include:

- **Child Restraint Anchors** - All vehicles are equipped with three, fixed-position, child seat upper tether anchors for the second row seat. Two anchors are integral to the back of the right second row seat cushion frame, and one is integral to the left second row seat cushion frame. The upper tether anchors are accessed from behind the second row seats. Two lower anchors are also provided for each outboard second row seating position, while only one lower anchor is provided for the center seating position. These lower anchors are also integral to the second row seat cushion frames. The lower anchors are all accessed from the front of the second row seats, where the seat back meets the seat cushion.
- **Front Seat Belts** - Both front seating positions are equipped with three-point seat belt systems employing lower B-pillar mounted inertia latch-type emergency locking retractors, height-adjustable upper B-pillar mounted turning loops, a traveling lower seat belt anchor secured to the outboard side of the seat frame, and a traveling end-release seat belt buckle secured to the inboard side of the seat frame. The passenger side front seat belt retractor is switchable to an automatic locking retractor for compatibility with child seats. The driver and passenger side front seat belt buckles each include an integral seat belt switch that detects whether the front seat belts have been fastened.
- **Integrated Child Booster Seats** - Two integrated child booster seats are an available option. Vehicles with this option have a booster seat integral to each of the two outboard second row seating positions. The center section of the seat cushion of these seats is lifted up and rearward to raise the seat cushion. These booster seats raise a child aged four and older, weighing over 18.14 kilograms (40 pounds) and up to 144.78 centimeters (57 inches) tall into the belted zone of the adult seat belts.
- **Second Row Seat Belts** - All second row seating positions are equipped with three-point seat belt systems. The outboard seating position belts employ C-pillar mounted inertia latch-type emergency locking retractors, fixed position upper C-pillar mounted turning loops and fixed lower seat belt anchors secured to the floor panel. The second row center seating position belt has an inertia latch-type emergency locking retractor that is integral to the right second row seat back panel. The second row center seating position belt lower anchor is secured to the second row right seat cushion frame. All three rear seat belts have fixed end-release seat belt buckles secured to the seat cushion frames, a double buckle unit on the left side and a single buckle unit on the right side. Both outboard second row seat belt retractors are switchable to an automatic locking retractor for compatibility with child seats.
- **Third Row Seat Belts** - In vehicles equipped with the optional third row bench seat, both third row seating positions are equipped with three-point seat belt systems. These belts employ lower D-pillar mounted inertia latch-type emergency locking retractors, fixed position upper D-pillar mounted turning loops, fixed lower seat belt anchors and fixed position end-release buckles secured to the floor panel. Both third row seat belt retractors are switchable to an automatic locking retractor for compatibility with child seats.

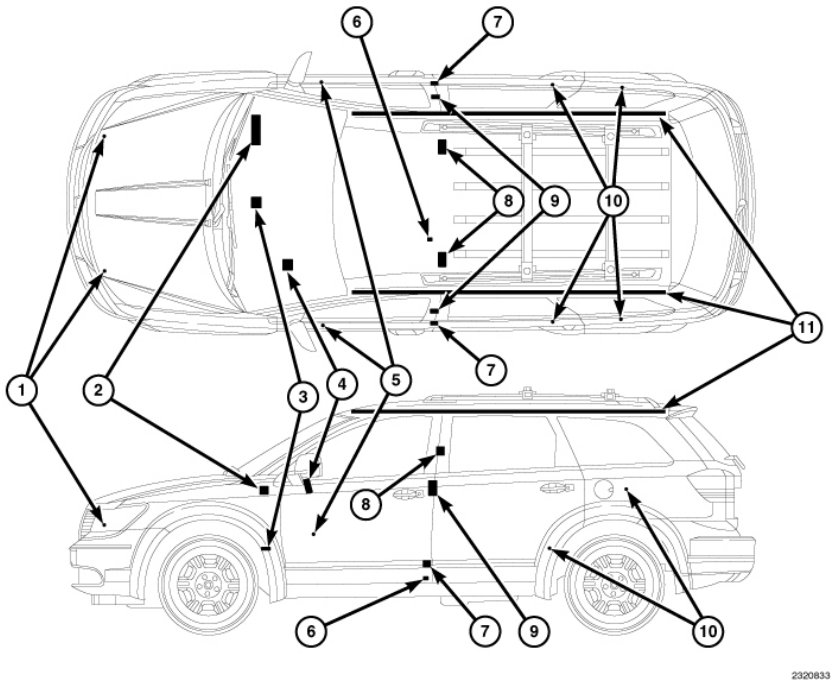
PASSIVE RESTRAINTS

The passive restraints available for this vehicle include the following:

8098029e

- **Active Head Restraints** - Active Head Restraints (AHR) are standard equipment for both front seating positions in this vehicle. An AHR can be readily distinguished from a non-active head restraint by the two-piece construction used for an AHR. The forward-facing surface is padded and covered in a material coordinated with the other soft trim on the seat, while the rearward-facing surface is equipped with a molded plastic trim cover that matches the other hard trim on the seat.
- **Dual Front Airbags** - A multistage Driver AirBag (DAB) and front Passenger AirBag (PAB) are used in this vehicle. This airbag system consists of passive, inflatable, Supplemental Restraint System (SRS) components and vehicles with this equipment can be readily identified by the **SRS - AIRBAG** logo molded into the DAB trim cover in the center of the steering wheel and also into the PAB door on the top of the instrument panel above the glove box. Vehicles with the airbag system can also be identified by the airbag indicator, which will illuminate in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) from four to six seconds as a bulb test each time the ignition switch is turned to the On position. Pyrotechnic-type seat belt tensioners are also included for the driver and passenger front seat belts of all airbag equipped vehicles to work in conjunction with the dual front and side curtain airbags.
- **Knee Airbag** - In domestic market vehicles, the front airbag system also includes a Knee AirBag (KAB) (also known as a Inflatable Knee Blocker/IKB) that is located just below the steering column, behind the instrument panel steering column opening cover. This airbag is also a passive, inflatable, SRS component and vehicles with this equipment can be readily identified by the **SRS - AIRBAG** logo molded into the steering column opening cover on the instrument panel just beneath the steering column.
- **Seat Airbags** - Front seat integrated Seat AirBags (SAB) (also known as pelvic and thoracic airbags) are standard equipment in this vehicle in all markets except Mexico, where they are optional. This airbag system consists of passive, inflatable, SRS components and vehicles with this equipment can be readily identified by a sewn tag with the **SRS - AIRBAG** logo located on the outboard side of the front seat back trim cover.
- **Side Curtain Airbags** - Side curtain airbags (also known as Side AirBag Inflatable Curtains/SABIC) are standard equipment for this vehicle when it is also equipped with dual front airbags. This airbag system consists of passive, inflatable SRS components and vehicles with this equipment can be readily identified by a molded identification trim plug with the **SRS - AIRBAG** logo located near the tops of the B and C-pillar trim.



2320833

The SRS includes the following major components, which are described in further detail elsewhere in this service information:

- **Active Head Restraints (8)** - On vehicles with this equipment, one Active Head Restraint (AHR) is located atop each front seat back unit.

- **Airbag Indicator** - The airbag indicator is integral to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC), which is located on the instrument panel in front of the driver.
- **Clockspring** - The clockspring is located near the top of the steering column, directly beneath the steering wheel.
- **Driver Airbag (4)** - The Driver AirBag (DAB) is located in the center of the steering wheel, beneath the DAB trim cover.
- **Driver Knee Blocker** - The driver knee blocker is a static structural unit secured to the back side of and integral to the instrument panel steering column opening cover.
- **Front Impact Sensor (1)** - Two front impact sensors are used on vehicles equipped with dual front airbags, one left side and one right side. One sensor is located on the back side of the front end module carrier on either side of the radiator and inboard of the headlamp within the engine compartment.
- **Knee Airbag** - Vehicles manufactured for domestic markets are equipped with a Knee AirBag (KAB) (also known as a Inflatable Knee Blocker/IKB) feature. The KAB is mounted behind the instrument panel steering column opening cover in addition to the static driver knee blocker.
- **Occupant Restraint Controller (3)** - The Occupant Restraint Controller (ORC) is located on a mount on the floor panel transmission tunnel forward of the transmission gear selector, and is concealed beneath the center front floor mini console.
- **Passenger Airbag (2)** - The Passenger AirBag (PAB) is located in the instrument panel, beneath the PAB door on the top of the instrument panel above the glove box on the passenger side of the vehicle.
- **Passenger Knee Blocker** - The passenger knee blocker is a static structural reinforcement that is integral to and concealed within the glove box door.
- **Seat Airbag (9)** - On vehicles so equipped, a Seat AirBag (SAB) (also known as a pelvic and thoracic airbag) is secured to each outboard front seat back frame, where it is concealed beneath the seat back trim cover and foam.
- **Seat Belt Tensioner (7)** - A seat belt retractor tensioner unit is integral to both front seat belt retractor units on vehicles for all markets equipped with dual front airbags. The seat belt retractor and tensioner units are secured to each lower inner B-pillar and are concealed behind the lower B-pillar trim. In addition, a seat belt buckle tensioner unit is integral to the passenger side front seat belt buckle on all domestic market vehicles equipped with dual front airbags. The seat belt buckle tensioner units are located on the inboard rear corner of the right front seat cushion frame.
- **Seat Track Position Sensor** - Certain vehicles may include a Seat Track Position Sensor (STPS) that may be located on the inboard side of the upper inboard seat adjuster track on both the driver and the passenger front seats.
- **Side Curtain Airbag (11)** - A side curtain airbag (also known as a Side AirBag Inflatable Curtain/SABIC) is secured to each inside roof side rail above the headliner, and extends from the A-pillar to just beyond the C-pillar on vehicles with standard five-passenger seating, or from the A-pillar to the D-pillar on vehicles with optional seven-passenger seating.
- **Side Impact Sensor (5 and 10)** - Six side impact sensors are standard equipment on vehicles equipped with side curtain airbags and the five-passenger seating package, three on each side of the vehicle. Eight side impact sensors are used on vehicles equipped with side curtain airbags and the seven-passenger seating package, four on each side of the vehicle. One pressure-type sensor (5) is located on each right and left side front door hardware module carrier of all vehicles with side curtain airbags, while one acceleration-type sensor (9) is located on each B and C-pillar. The seven-passenger seating package adds another acceleration-type D-pillar sensor to each quarter inner panel above the rear wheel houses. These sensors are each concealed behind their adjacent interior trim components.

The ORC and the IC each contain a microcontroller and programming that allow them to communicate with each other using the Controller Area Network (CAN) data bus. This method of communication is used by the ORC for control of the airbag indicator in the IC. (Refer to 08 - Electrical/8E - Electronic Control Modules/COMMUNICATION - Description) .

Hard wired circuitry connects the SRS components to each other through the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system, and to the SRS components through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin out and location views for the various wire harness connectors, splices and grounds.

PEDESTRIAN PROTECTION SYSTEM

An Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System) is factory-installed safety equipment, which is available only in vehicles manufactured for certain export markets. The EPP system includes the following major components, which are described in further detail elsewhere in this service information:

- **Active Hood Hinge Actuators** - The two pyrotechnic EPP active hood hinge actuators are each secured by a screw within a mounting plate located on each of the two active hood hinges, which are located near each rear corner of the hood panel.
- **Active Hood Hinges** - The active hood hinges have several features and components not found on a conventional hood hinge. In addition to a mounting plate for a pyrotechnic actuator and a reset spring, each active hood hinge includes a mid-strap joined to the hood bracket by a pivot pin at the forward end and a shear rivet at the rearward end. An up-stop pin near the center of the mid-strap fits within a slotted hole near the center of the hood bracket. Refer to Group 23 - Body for hood hinge removal and installation procedures.
- **Electronic Pedestrian Protection Module** - The Electronic Pedestrian Protection Module (EPPM) is located on a stamped metal mounting bracket on the floor panel beneath the left front seat. The mounting bracket is secured to four weld studs on the floor panel by four hex nuts. The EPPM has a molded plastic protective cover snapped over the top.
- **Front Energy Absorber Foam Material** - The front energy absorber foam material is sandwiched between the front bumper area of the front fascia and the front bumper support beam. Refer to Group 13 - Frame And Bumpers for front fascia removal and installation procedures.
- **Impact Sensors** - The EPP system includes three dedicated acceleration-type impact sensors to support the EPP feature. The impact sensors are each mounted by a hex nut to a weld stud within a dedicated bracket located on the top surface of the front bumper support beam. One sensor and bracket is located near each end of the bumper support beam, and one is located near the center. The impact sensors and brackets are concealed behind the front fascia.
- **Pedestrian Bar** - A static, tubular metal pedestrian bar (also known as a leg catcher) is concealed just behind the lower end of the front fascia. The pedestrian bar is suspended at each side from the lower end of a stamped metal bracket that is secured at the top near the same brackets that support each end of the front bumper support beam. Refer to Group 13 - Frame and Bumpers for the pedestrian bar removal and installation procedures.
- **Safing Sensors** - The EPP system includes two dedicated acceleration-type safing sensors to support the EPP feature. The safing sensors are each mounted by a hex nut to a stud within a dedicated bracket located on the inner surface of the front fascia. One sensor and bracket is located just inboard of the fog lamp opening near each end of the front fascia.

The EPPM and the Occupant Restraint Controller (ORC) each contain a microprocessor and programming that allow them to communicate with each other using the Controller Area Network (CAN) data bus. This method of communication is also used by the ORC for control of the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC). (Refer to 08 - Electrical/8E - Electronic Control Modules/COMMUNICATION - Description) .

Hard wired circuitry connects the EPP electronic components to each other through the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system, and to the EPP components through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention as well as pin out and location views for the various wire harness connectors, splices and grounds.

SUPPLEMENTAL RESTRAINT SYSTEM

A Supplemental Restraint System (SRS) is standard factory-installed safety equipment on this vehicle. Available supplemental occupant restraints for this vehicle include both active and passive types. Active restraints are those which require the vehicle occupants to take some action to employ, such as fastening a seat belt; while passive restraints require no action by the vehicle occupants to be employed.

In addition, vehicles manufactured for certain export markets include the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System), which includes both dynamic and static elements designed to enhance the protection of pedestrians. Additional information on each of these subsystems of the SRS can be found elsewhere within this service information.

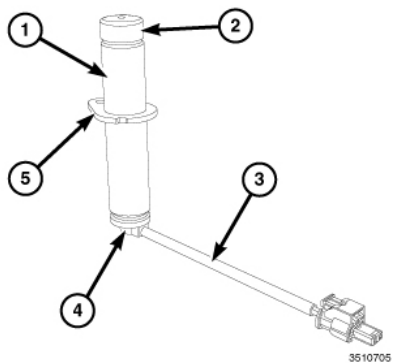
DESCRIPTION

Active hood hinge actuators are found only in vehicles equipped with the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or Active Hood System), which is available only in vehicles manufactured for certain export markets. An EPP active hood hinge actuator is located on each hinge. The actuators are secured by a self-tapping screw through an integral bracket (5) to a mounting plate integral to the rear of the lower bracket on each active hood hinge.

The actuator consists primarily of a tubular metal housing (1) containing a metal piston (2) with a molded plastic cap and a small pyrotechnically activated gas generator (4). The actuators are controlled by the Electronic Pedestrian Protection Module (EPPM). An actuator pigtail wire (3) and connector insulator are routed to a dedicated take out of the headlamp and dash wire harness and connected to the vehicle electrical system by a keyed and latching molded plastic connector insulator to ensure a secure connection.



The EPP active hood hinge actuators cannot be repaired and, if ineffective or damaged, the entire actuator unit must be replaced. The actuators are not intended for reuse and must be replaced following any EPP system deployment.

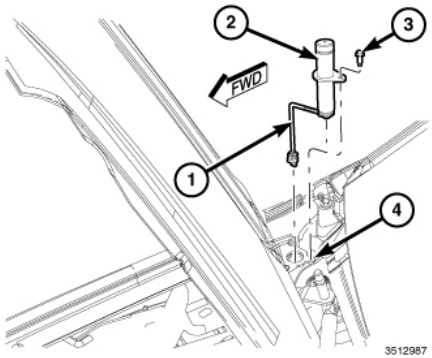
INSTALLATION

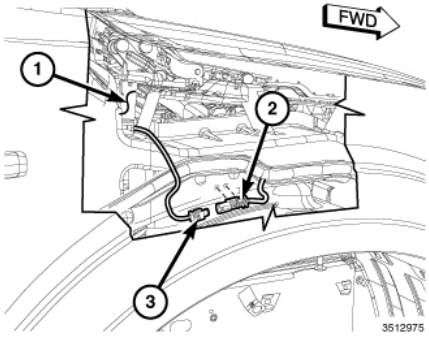
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with the Electronic Pedestrian Protection (EPP) system, disable the system before attempting any EPP system component diagnosis or service. With the ignition switch in the OFF position, disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the EPP system. Failure to take the proper precautions could result in accidental active hood hinge actuator deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Electronic Pedestrian Protection (EPP) system active hood hinge actuator. If the actuator is ineffective or damaged, but not deployed, it should be handled in the same manner as is used when handling non-deployed supplemental restraints. Review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the actuator has been deployed, review the recommended procedures for Service After A Pedestrian Protection Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Guide the pigtail wire (1) and connector of the Electronic Pedestrian Protection (EPP) active hood hinge actuator (2) through the mount (4) at the back of the hood hinge lower bracket while positioning the actuator to the hinge.
2. Align the hole in the actuator bracket with the hole in the hinge mount.
3. Install and tighten the screw (3) that secures the actuator to the hinge. Tighten the screw to 7.9 N·m (70 in. lbs.).
4. Reconnect the pigtail wire connector (3) of the actuator (1) to the headlamp and dash wire harness connector (2).
5. Reinstall the splash shield into the right or left front wheel house. (Refer to 23 - Body/Exterior /SHIELD, Splash - Installation) .
6. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any EPP system component. (Refer to 10 - Restraints - Standard Procedure) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Electronic Pedestrian Protection (EPP) active hood hinge actuators are deployed by a signal generated by the Electronic Pedestrian Protection Module (EPPM) through the right and left hood actuator line 1 and line 2 (or squib) circuits. When the EPPM sends the proper electrical signal to the actuators, the electrical energy generates enough heat to initiate a small pyrotechnic gas generator.

The gas generator is installed in one end of a steel cylinder tube where the piston is sealed to the inside circumference of the tube. As the gas expands, it pushes the piston up the tube, where it actuates the leveraging mechanism of the active hood hinge that cuts the hinge shear rivet and raises the rear edge of the hood panel.

Raising the hood panel following a frontal impact of the vehicle creates additional clearance between the hood and the hard components within the engine compartment. This clearance helps to reduce the severity of injuries that a pedestrian might experience in these situations as a result of harmful contact with those hard parts found just beneath the hood panel within the engine compartment.

The EPPM monitors the condition of the active hood hinge actuators through circuit resistance, and will register a Diagnostic Trouble Code (DTC) for any fault that is detected. The Occupant Restraint Controller (ORC) continually monitors the EPPM and when the EPPM registers a DTC, the ORC will request illumination of the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC). Proper diagnosis of the active hood hinge actuator gas generator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

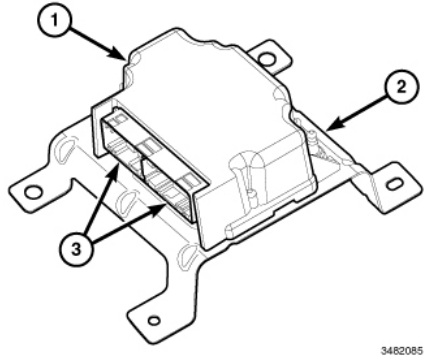
DESCRIPTION

The Electronic Pedestrian Protection Module (EPPM) (1) is found only in vehicles equipped with the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System), which is available only in vehicles manufactured for certain export markets. The EPPM is secured to a stamped metal mounting bracket (2). The EPPM and mounting bracket unit is secured by four hex nuts to four weld studs on the floor panel just behind the front seat cross member under the left front seat.

Concealed within a hollow in the center of the die cast aluminum EPPM housing is the electronic circuitry of the module which includes a microcontroller and an energy storage capacitor. A stamped metal cover plate is secured to the bottom of the EPPM housing with screws to enclose and protect the internal electronic circuitry and components.

A molded plastic electrical connector (3) with two receptacles containing numerous terminal pins, exits the inboard facing side of the EPPM housing. These terminal pins connect the EPPM to the vehicle electrical system through two dedicated take outs and connectors from the body wire harness.



The EPPM cannot be repaired or adjusted and, if damaged or ineffective, it must be replaced. The EPPM and the stamped metal mounting bracket are serviced only as a unit.

OPERATION

The microcontroller within the Electronic Pedestrian Protection Module (EPPM) contains the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System) logic circuits. The EPPM receives battery current through a fused ignition switch output (run-start) circuit and a fuse in the Power Distribution Center (PDC). The EPPM receives ground through two ground circuits and a take out of the body wire harness that is secured by a ground screw to the body sheet metal. These connections allow the EPPM to be operational whenever the status of the ignition switch is Start or On.

The EPPM uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool using the Controller Area Network (CAN) data bus. This method of communication is also used by the Occupant Restraint Controller (ORC) to monitor the EPPM and for EPP system diagnosis and testing through the 16-way data link connector located on the driver side lower edge of the instrument panel.

The EPPM logic continuously monitors the three primary EPP acceleration-type electronic impact sensors located on the top of the front bumper support beam at the front of the vehicle as well as the two dedicated EPP acceleration-type electronic safing sensors located on the inside surface of the front bumper fascia. The impact sensors are accelerometers that sense the rate of vehicle deceleration, which provides an input indicating the direction and severity of an impact. The safing sensors are accelerometers that also sense the rate of vehicle deceleration, which provides additional verification of the direction and severity of an impact.

The EPPM also monitors electronic **ignition status**, **vehicle speed** and **ambient temperature** message inputs received from other electronic modules over the CAN data bus. The EPPM uses a pre-programmed decision algorithm to analyze all of these inputs, which allows the EPPM to determine both the type and severity of an impact.

When the deceleration rate as signaled by the primary impact sensors and confirmed by the safing sensors indicate an impact that requires the deployment of the pyrotechnic EPP actuator located on each active hood hinge at the rear corners of the hood panel and all other programmed conditions are met, the EPPM sends the proper electrical signals to deploy the actuators. As a safing function, the EPPM requires confirming sensor inputs from at least one of the two EPP safing sensors located on the front fascia before it will issue a deployment signal.

The EPPM also contains an energy-storage capacitor. When the status of the ignition switch is Start or On, this capacitor is continually being charged with enough electrical energy to deploy the active hood hinge actuators for up to one second following a battery disconnect or failure. The purpose of the capacitor is to provide backup EPP system protection in case there is a loss of battery current supply to the EPPM during an impact event.

An Event Data Recorder (EDR) within the EPPM stores both deployment event and near-deployment event records. The near-deployment records can be overwritten, the deployment records cannot. After three deployment records have been stored, a **Deployment Data Record Full** Diagnostic Trouble Code (DTC) is logged. Once the **Deployment Data Record Full** DTC is logged, the EPPM and both active hood hinges **must** be replaced with new units.

The EPPM microcontroller continuously monitors all of the EPP system electrical circuits to determine the system readiness. If the EPPM detects a monitored system fault, it logs an active DTC. The EPPM also stores a DTC after it has been resolved. The ORC continually monitors the EPPM and, when it detects that the EPPM has logged a DTC, it sends electronic request messages over the CAN data bus to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) to turn On the airbag indicator.

The hard wired inputs and outputs for the EPPM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the EPPM or the electronic controls and communication between other modules and devices that provide features of the EPP system. The most reliable, efficient and accurate means to diagnose the EPPM or the electronic controls and communication related to EPP system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

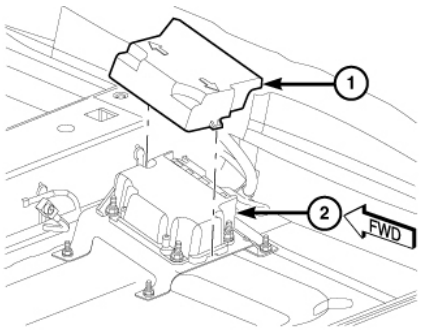
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with the Electronic Pedestrian Protection (EPP) system, disable the system before attempting any EPP system component diagnosis or service. With the ignition switch in the OFF position, disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the EPP system. Failure to take the proper precautions could result in accidental active hood hinge actuator deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Electronic Pedestrian Protection Module (EPPM). If the Electronic Pedestrian Protection (EPP) system has been deployed, review the recommended procedures for Service After A Pedestrian Protection Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



3494845

1. Move the left front seat to the most forward and most raised position for easiest access to the Electronic Pedestrian Protection Module (EPPM) (2).
2. With the status of the ignition switch Off, disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
3. Working from behind the left front seat, locate the EPPM on the floor panel under the left front seat.
4. The EPPM cover (1) is secured to the EPPM (2) by a latch tab located on the forward and rearward sides of the cover. Gently pry both latch tabs away from the EPPM far enough to disengage the latches from the slots in the base of the EPPM housing, then lift the cover off of the EPPM.
5. Disconnect the two body wire harness connectors (2) from the EPPM connector receptacles located on the inboard facing side of the module. To disconnect the wire harness connectors from the EPPM, depress the release tab and lift the lever arm to the fully open position on each connector.
6. Remove the four nuts (3) that secure the EPPM mounting bracket to the four weld studs on the floor panel.
7. Lift the EPPM and mounting bracket unit far enough to disengage the mounting bracket from the weld studs and remove the EPPM and mounting bracket unit from under the seat.

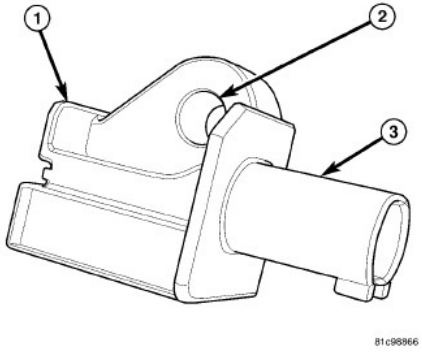
ACCELERATION TYPE

Remote or satellite acceleration-type impact sensors (1) are mounted in various locations in the vehicle. These sensors are mounted remotely from the impact sensor that is internal to the Occupant Restraint Controller (ORC). Sensors at the front of the vehicle provide an additional logic input for use by the ORC to control the front airbags and the seat belt pretensioners. Sensors on each side of the vehicle provide an additional logic input for use by the ORC to control the side curtain airbags, the seat belt pretensioners and the seat (also known as pelvic and thorax) airbags.



Although the front and side acceleration-type impact sensors are similar in appearance and construction, they may not be interchangeable. The front impact sensors may monitor acceleration forces on a different axis than those monitored by the side impact sensors. The sensor housing has an integral connector receptacle (3), an integral locating and anti-rotation pin, and an integral mounting hole (2). A cavity in the center of the molded plastic impact sensor housing contains the electronic circuitry of the sensor which includes an electronic communication chip and an electronic acceleration sensor. Potting material fills the cavity to seal and protect the internal electronic circuitry and components.

Each front sensor is secured with a screw to the back of the Front End Module (FEM) carrier on either side of the cooling module, just below the inboard end of each front lamp unit housing within the engine compartment. The front impact sensors are each connected to the vehicle electrical system through a dedicated take out and connector of the FEM wire harness.

Two B-pillar and two C-pillar side impact sensors are used on this vehicle, one each for the left and right sides of the vehicle. Each B-pillar sensor is secured with a screw to the lower B-pillar just above the sill within the passenger compartment. Each C-pillar sensor is secured with a screw to the lower C-pillar just above the rear door opening sill within the passenger compartment. The right and left B-pillar and C-pillar side impact sensors are identical in construction and calibration. However, the connector orientation in the vehicle is reversed. The connector receptacle faces forward on the right side of the vehicle, and faces rearward on the left side of the vehicle. The B-pillar and C-pillar side impact sensors are each connected to the vehicle electrical system through a dedicated take out and connector of the body wire harness.

Two D-pillar side impact sensors are used on this vehicle when it is equipped with the side curtain airbags and seven-passenger seating, one each for the left and right sides of the vehicle. Each D-pillar sensor is secured with a screw to the right or left quarter inner panel just above the right or left rear wheel housing within the passenger compartment. The right and left D-pillar side impact sensors are identical in construction and calibration. However, the connector orientation in the vehicle is reversed. The connector receptacle faces forward on the right side of the vehicle, and faces rearward on the left side of the vehicle. The D-pillar side impact sensors are each connected to the vehicle electrical system through a dedicated take out and connector of the body wire harness.

The acceleration-type impact sensors cannot be repaired or adjusted and, if damaged or ineffective, they must be replaced.

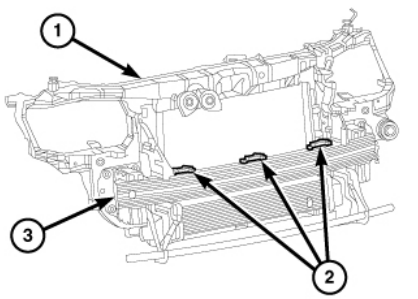
ELECTRONIC PEDESTRIAN PROTECTION

Electronic Pedestrian Protection (EPP) impact sensors (2) are found only in vehicles equipped with the EPP system (also known as the PedPro or Active Hood System), which is available only in vehicles manufactured for certain export markets. These sensors are mounted at the front of the vehicle to provide an additional logic input for use by the Electronic Pedestrian Protection Module (EPPM) to control the pyrotechnic EPP active hood hinge actuators located on each hinge at the rear corners of the hood panel.

The EPP impact sensors are satellite acceleration-type sensors that are mounted to the front bumper support beam (3) at the front of the Front End Module (FEM) (1) in the vehicle. The three sensors are each secured by a nut to a weld stud within a dedicated bracket on the top of the front bumper support beam. The sensors and the front bumper support beam are concealed behind the front fascia.



3480628

Each sensor housing (1) has an integral connector receptacle (4), an integral locator pin (3) and an integral mounting hole with a metal sleeve (2) to provide crush protection. A cavity in the center of the molded plastic impact sensor housing contains the electronic circuitry of the sensor which includes an electronic communication chip and an electronic acceleration sensor. Potting material fills the cavity and a translucent molded cover is laser welded over the cavity to seal and protect the internal electronic circuitry and components.

The EPP impact sensors are each connected to the vehicle electrical system through dedicated take outs and connectors of the headlamp and dash wire harness. The two outboard EPP impact sensors are connected to the EPPM in a daisy chain through the EPP safing sensors on the back of the front fascia. These acceleration-type impact sensors cannot be repaired or adjusted and, if damaged or ineffective, they must be replaced.

IMPACT SENSORS

Remote or satellite impact sensors are mounted in various strategic locations of the vehicle. These sensors are mounted remotely from the impact sensor that is internal to the Occupant Restraint Controller (ORC). Sensors at the front of the vehicle provide an additional logic input for use by the Occupant Restraint Controller (ORC) to control the front airbags and the seat belt pretensioners. Sensors on each side of the vehicle provide an additional logic input for use by the ORC to control the side curtain airbags, seat airbags and the seat belt pretensioners. In addition, in vehicles manufactured for sale in certain export markets where the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System) is factory-installed safety equipment, sensors located behind the front fascia provide an additional logic input for use by the ORC to control the active hood actuators.

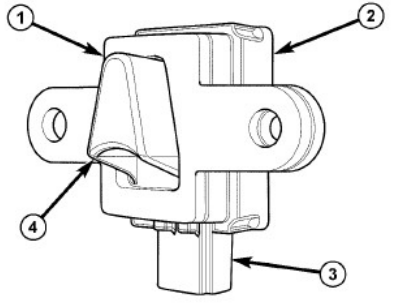
Two types of sensors are used in this vehicle. They are the acceleration-type and the pressure-type, which are described in further detail elsewhere within this service information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

PRESSURE TYPE

Two pressure-type front door side impact sensors (2) are used on this vehicle when it is equipped with the side curtain airbags or the optional seat (also known as thorax) airbags, one each for the left and right sides of the vehicle. These sensors are mounted remotely from the impact sensor that is internal to the Occupant Restraint Controller (ORC). Each side sensor is secured with two screws and is sealed by a resilient gasket (1) to the front door module carrier on the inside of the front door. The sensors are concealed behind the front door trim panel within the passenger compartment.



The right and left front door side impact sensors are identical in construction and calibration. The impact sensor housing has an integral connector receptacle (3), two integral mounting tabs, and an integral hood-like water shield (4) that extends through a hole in the front door module carrier into the interior of the door cavity and protects the sensor orifice from contamination. A cavity in the center of the molded plastic impact sensor housing contains the electronic circuitry of the sensor, which includes an electronic communication chip and the pressure sensor. The housing cavity is filled with a potting material to seal and protect the internal electronic circuitry and components. A label on the sensor has a directional arrow and the word **down** imprinted upon it to provide verification of the correct sensor orientation in the vehicle. The side impact sensors are each connected to the vehicle electrical system through a dedicated take out and connector of the front door wire harness.

These pressure-type front door side impact sensors cannot be repaired or adjusted and, if damaged or ineffective, they must be replaced.

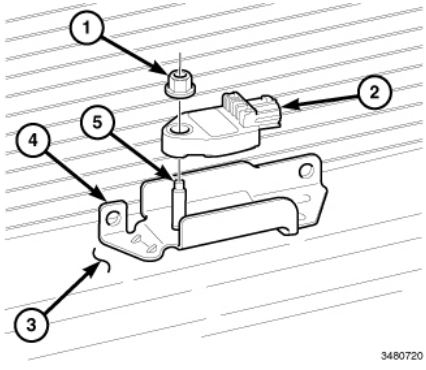
ELECTRONIC PEDESTRIAN PROTECTION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with the Electronic Pedestrian Protection (EPP) system, disable the system before attempting any EPP system component diagnosis or service. With the ignition switch in the OFF position, disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the EPP system. Failure to take the proper precautions could result in accidental active hood hinge actuator deployment.**

WARNING: **To avoid serious or fatal injury, never strike or drop the Electronic Pedestrian Protection (EPP) system impact sensor, as it can damage the impact sensor or affect its calibration. The EPP impact sensor enables the system to deploy the EPP system active hood hinge actuators. If an impact sensor is accidentally dropped during service, the sensor must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper EPP active hood hinge actuator deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Electronic Pedestrian Protection (EPP) system impact sensor. Whether the EPP system has been deployed or the vehicle has had a front end collision without EPP system deployment, review the recommended procedures for Service After A Pedestrian Protection Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Carefully position the right, left or center Electronic Pedestrian Protection (EPP) impact sensor (2) onto the weld stud (5) within the bracket (4) on the top of the front bumper support beam (3). Be certain that the anti-rotation pin on the back of the sensor is engaged in the clearance hole of the bracket.
2. Install and tighten the nut (1) that secures the sensor to the weld stud. Tighten the nut to 8 N·m (70 in. lbs.).
3. Reconnect the headlamp and dash wire harness connector to the right, left or center EPP impact sensor connector receptacle.
4. Reinstall the front fascia onto the vehicle. (Refer to 13 - Frame and Bumpers/Bumpers/FASCIA, Front - Installation) .
5. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any EPP component. (Refer to 10 - Restraints - Standard Procedure) .

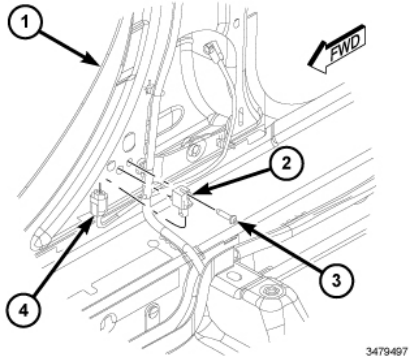
SIDE - B-PILLAR

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, never strike or drop the side impact sensor, as it can damage the impact sensor or affect its calibration. The side impact sensor enables the system to deploy the side Supplemental Restraint System (SRS) components. If an impact sensor is accidentally dropped during service, the sensor must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper side SRS component deployment.**

NOTE: The front and the B, C or D-pillar side impact sensors are interchangeable.



1. Position the side impact sensor (2) to the lower B-pillar (1).
2. Align the anti-rotation pin on the base of the sensor with the clearance hole in the lower B-pillar, then press on the sensor firmly and evenly to snap the pin into place.
3. Install and tighten the screw (3) that secures the side impact sensor to the lower B-pillar. Tighten the screw to 9 N·m (80 in. lbs.).
4. Reconnect the body wire harness connector (4) to the side impact sensor on the lower B-pillar.
5. Reinstall the trim onto the lower B-pillar. (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Installation) .
6. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

ACCELERATION TYPE

The acceleration-type impact sensors are electronic accelerometers that sense the rate of vehicle deceleration, which provides verification of the direction and severity of an impact. Each sensor also contains an electronic communication chip that allows the unit to communicate the sensor status as well as sensor fault information to the microcontroller within the Occupant Restraint Controller (ORC).

The ORC microcontroller continuously monitors all of the passive restraint system electrical circuits to determine the system readiness. If the ORC detects a monitored system fault, it sets a Diagnostic Trouble Code (DTC) and controls the airbag indicator operation accordingly. The impact sensors each receive battery current and ground through dedicated left and right sensor plus and minus circuits from the ORC. The impact sensors and the ORC communicate by modulating the voltage in the sensor plus circuit.

The hard wired circuits between the impact sensors and the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the impact sensors or the electronic controls and communication between other modules and devices that provide some features of the Supplemental Restraint System (SRS). The most reliable, efficient and accurate means to diagnose the acceleration-type impact sensors or the electronic controls and communication related to impact sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

ELECTRONIC PEDESTRIAN PROTECTION

The acceleration-type Electronic Pedestrian Protection (EPP) impact sensors are electronic accelerometers that sense the rate of vehicle deceleration, which provides verification of the direction and severity of an impact. Each sensor also contains an electronic communication chip that allows the unit to communicate the sensor status as well as sensor fault information to the microcontroller within the Electronic Pedestrian Protection Module (EPPM).

The EPPM microcontroller continuously monitors all of the EPP system electrical circuits to determine the system readiness. If the EPPM detects a monitored system fault, it sets a Diagnostic Trouble Code (DTC). The ORC continually monitors the EPPM and, when it detects that the EPPM has logged a DTC, it sends electronic request messages over the CAN data bus to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) to turn ON the airbag indicator. The EPPM also stores a DTC after the fault has been resolved. The impact sensors each receive battery current and ground through the dedicated left and right sensor plus and minus circuits from the EPPM. The impact sensors and the EPPM communicate by modulating the voltage in the sensor plus circuit.

The hard wired circuits between the acceleration-type EPP impact sensors and the EPPM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the impact sensors or the electronic controls and communication between other modules and devices that provide features of the EPP system. The most reliable, efficient and accurate means to diagnose the impact sensors or the electronic controls and communication related to acceleration-type EPP impact sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

IMPACT SENSORS

Two types of impact sensors are used in this vehicle. They are the acceleration-type and the pressure-type. In addition, in vehicles manufactured for sale in certain export markets where the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System) is factory-installed safety equipment have dedicated acceleration-type sensors for that feature. Additional operational details of each of these sensor types is described in further detail elsewhere within this service information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

PRESSURE TYPE

The pressure-type front door side impact sensors recognize a side impact in the front door area by monitoring changes in pressure within the front door cavity, which manifests itself as a sudden pressure wave as the door collapses during an impact. Each sensor also contains an electronic communication chip that allows the unit to communicate the sensor status as well as sensor fault information to the microcontroller within the Occupant Restraint Controller (ORC).

The ORC microcontroller continuously monitors all of the side passive restraint system electrical circuits to determine the system readiness. If the ORC detects a monitored system fault, it sets a Diagnostic Trouble Code (DTC) and controls the airbag indicator operation accordingly. The impact sensors each receive battery current and ground through dedicated left and right sensor plus and minus circuits from the ORC. The impact sensors and the ORC communicate by modulating the current in the sensor plus circuit.

The hard wired circuits between the pressure-type front door side impact sensors and the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the impact sensors or the electronic controls and communication between other modules and devices that provide features of the Supplemental Restraint System (SRS). The most reliable, efficient and accurate means to diagnose the pressure-type front door side impact sensors or the electronic controls and communication related to side impact sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

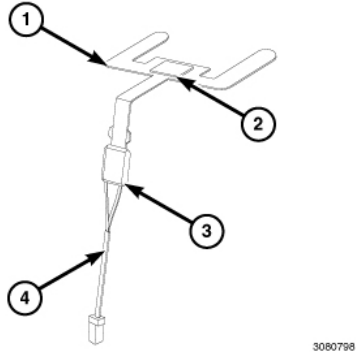
DESCRIPTION

An Occupant Detection Sensor (ODS) is located below the passenger side front seat cushion trim cover. On vehicles without the optional heated seats, the sensor is located on top of the cushion foam directly beneath the trim cover. On vehicles with the optional heated seats, the sensor is still located on top of the cushion foam, but is covered by the seat cushion heater mat. This sensor provides information to the Occupant Restraint Controller (ORC) used for control of the passenger belt alert feature.

The ODS consists of a flexible clear plastic sensor mat (1) containing several resistive membrane, force sensing resistor cells that is secured by adhesive strips (2) to the top surface of the seat cushion foam and, if the vehicle is so equipped, beneath the heater element mat. There are two versions of the sensor used that are similar, but not interchangeable. One version is for vehicles with a base seat without the fold flat seat option, and one version is for vehicles with the fold flat seat option.

On the base seat, the short, two-conductor pigtail wire and connector (4) are oriented toward the rear of the seat cushion, while the fold flat seat has the pigtail wire oriented toward the front of the seat cushion. Either pigtail wire connects the sensor to the vehicle electrical system through a dedicated take out and connector of the seat wire harness. A hot melt adhesive block (3) encapsulates and protects the connections between the electrical conductors in the tail of the sensor mat and the pigtail wires as well as a diagnostic resistor.



The ODS cannot be adjusted or repaired, and must be replaced if damaged or ineffective. On vehicles without the heated seat option, the sensor is available for separate service replacement. On vehicles with the heated seat option, the sensor is serviced as a unit with the seat cushion foam and the heater mat.

INSTALLATION

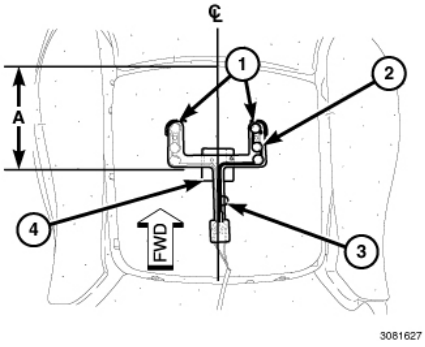
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **When handling a new Occupant Detection Sensor (ODS), it should never be bent, creased, torn, cut or abraded. The ODS should not be handled with or come into contact with hard or sharp-edged tools or objects. Do not allow the ODS to drop more than 2 meters (6.5 feet). Prior to installation, do not sit on, stand on or place boxes, tools or any other foreign object on the ODS. If the ODS adhesive patches become inadvertently adhered to any seat materials or foreign objects prior to proper positioning on the seat cushion, the ODS must be scrapped and replaced with a new unit. Do not modify the seat foam or trim materials of a seat that contains an ODS. Failure to observe these cautions may result in an inoperative ODS, or an ODS that provides inaccurate inputs to the Occupant Restraint Controller (ORC).**

BASE SEAT

NOTE: On vehicles without the heated seat option, the Occupant Detection Sensor (ODS) is available for separate service replacement. On vehicles with the heated seat option, the ODS is serviced ONLY as a unit with the seat cushion foam and the cushion heater mat.



3081627

1. Mark the Center Line (CL) of the seat cushion on the top of the seat cushion foam.

CAUTION: **The adhesive used to secure the ODS to the seat is heat activated and requires that both the adhesive and the material it is applied to be ideally between 21° and 38° C (between 70° and 100° F). Application of the ODS to surfaces below 10° C (50° F) is not recommended as the adhesive becomes too firm to readily adhere. Do not touch or allow the adhesive patches to contact any foreign materials with the release paper removed. Do not attempt to add adhesive materials to the ODS.**

2. Peel the release paper (4) off of the two adhesive patches on the underside of the Occupant Detection Sensor (ODS) mat (2).
3. Carefully position the ODS mat onto the seat cushion with the label between the branches containing the circular sensor cells centered on the marked seat cushion center line ± 5 millimeters (0.196 inches), and front-to-rear (A) with the back edge of the ODS mat positioned 185 ± 5 millimeters (7.283 inches ± 0.196 inches) rearward of the back edge of the front crimp channel in the seat cushion foam. The foam has cutouts (1) to aid in proper ODS mat positioning.
4. Apply hand pressure (0.8 bar or 12 psi) over each of the two adhesive patches of the ODS mat for at least four seconds to activate and adhere the adhesive to the seat cushion foam.
5. Feed the ODS pigtail wires and the hot melt connection block through the clearance hole (3) in the seat cushion foam just rearward of the ODS mat.
6. Route the ODS pigtail wire under the rear of the seat cushion foam.
7. Reach under the back of the front seat cushion frame to access and reconnect the ODS pigtail wire connector to the seat wire harness.

8. Reinstall the trim onto the front seat cushion foam and frame. (Refer to 23 - Body/Seats/COVER, Seat Cushion - Installation) .

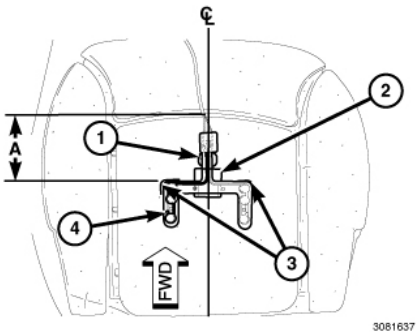
9. Reinstall the passenger side front seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .

10. Reconnect the negative cable to the battery.

FOLD FLAT SEAT

NOTE:

On vehicles without the heated seat option, the Occupant Detection Sensor (ODS) is available for separate service replacement. On vehicles with the heated seat option, the ODS is serviced ONLY as a unit with the seat cushion foam and the cushion heater mat.



1. Mark the Center Line (CL) of the seat cushion on the top of the seat cushion foam.

CAUTION:

The adhesive used to secure the ODS to the seat is heat activated and requires that both the adhesive and the material it is applied to be ideally between 21° and 38° C (between 70° and 100° F). Application of the ODS to surfaces below 10° C (50° F) is not recommended as the adhesive becomes too firm to readily adhere. Do not touch or allow the adhesive patches to contact any foreign materials with the release paper removed. Do not attempt to add adhesive materials to the ODS.

2. Peel the release paper (2) off of the two adhesive patches on the underside of the Occupant Detection Sensor (ODS) mat (4).

3. Carefully position the ODS mat onto the seat cushion with the label between the branches containing the circular sensor cells centered on the marked seat cushion center line ± 5 millimeters (0.196 inches), and front-to-rear (A) with the back edge of the ODS mat positioned 120 ± 5 millimeters (4.724 inches ± 0.196 inches) rearward of the back edge of the front crimp channel in the seat cushion foam. The foam has cutouts (3) to aid in proper ODS mat positioning.

4. Apply hand pressure (0.8 bar or 12 psi) over each of the two adhesive patches of the ODS mat for at least four seconds to activate and adhere the adhesive to the seat cushion foam.

5. Feed the ODS pigtail wires and the hot melt connection block through the clearance hole (1) in the seat cushion foam just forward of the ODS mat.

6. Route the ODS pigtail wire under the front of the seat cushion foam.

7. Reach under the front of the front seat cushion frame to access and reconnect the ODS pigtail wire connector to the seat wire harness.

8. Reinstall the trim onto the front seat cushion foam and frame. (Refer to 23 - Body/Seats/COVER, Seat Cushion - Installation) .

9. Reinstall the passenger side front seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .

10. Reconnect the negative cable to the battery.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Occupant Detection Sensor (ODS) acts as a simple switch to detect loads placed upon the passenger side front seat cushion. The sensor circuits are connected to and monitored by the Occupant Restraint Controller (ORC) whenever the ignition switch is in the ON position. The ORC uses an algorithm logic in monitoring the changing states of the sensor input to determine whether the seat cushion load is static or dynamic.

The ORC microcontroller continuously monitors all of the Supplemental Restraint System (SRS) electrical circuits to determine the system status and readiness. If the ORC detects a monitored system fault, it sets a Diagnostic Trouble Code (DTC). However, because the ODS input is only used for control of the passenger belt alert feature, which has no effect on SRS component features or functions, the airbag indicator is **NOT** illuminated in response to a detected ODS circuit fault.

The ODS receives source current and a clean ground through dedicated sensor plus and minus circuits from the ORC. The ORC then sends the appropriate sensor status information to the Body Control Module (BCM) (also known as the Common Body Controller/CBC), which uses this information as an additional logic input used for control of the seat belt indicator and the passenger belt alert feature in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC).

The hard wired circuits between the ODS and the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the ODS or the electronic controls and communication between other modules and devices that provide some features of the passenger belt alert feature. The most reliable, efficient and accurate means to diagnose the ODS or the electronic controls and communication related to the passenger belt alert feature operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

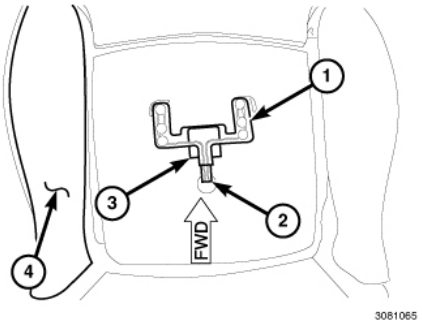
REMOVAL

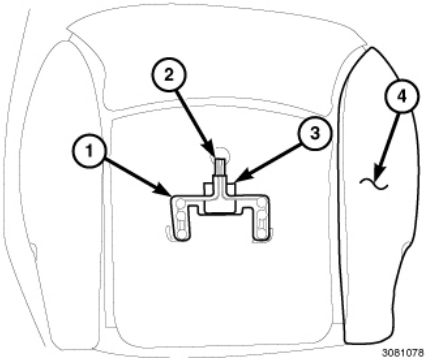
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**



Base Seat

NOTE: On vehicles with the heated seat option, the ODS is serviced ONLY as a unit with the seat cushion foam and the cushion heater mat.



Fold Flat Seat

1. Position the passenger side front seat to its most forward position for easiest access to the front seat mounting hardware.
2. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
3. Remove the passenger side front seat from the vehicle. (Refer to 23 - Body/Seats/SEAT - Removal) .
4. Remove the trim from the front seat cushion foam and frame. (Refer to 23 - Body/Seats/COVER, Seat Cushion - Removal) .

NOTE: The Occupant Detection Sensor pigtail wire is routed under the rear of the seat cushion foam on base seats, and under the front of the seat cushion foam on fold flat seats.

5. Reach under the seat cushion frame to access and disconnect the Occupant Detection Sensor (ODS) (1) pigtail wire connector from the seat wire harness.
6. Disengage the ODS hot melt block and pigtail wire from the clearance hole (2) in the seat cushion foam (4).

7. Disengage the two adhesive strips (3) of the ODS from the top surface of the seat cushion foam.

8. Remove the ODS from the seat cushion.

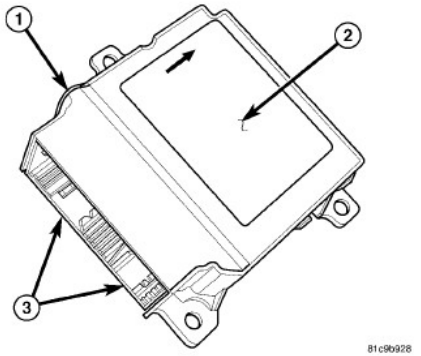
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The Occupant Restraint Controller (ORC) (1) is secured with three screws to a stamped steel mounting bracket welded onto the top of the floor panel transmission tunnel near the base of the dash panel and just forward on the center instrument panel support in the passenger compartment of the vehicle. Concealed within a hollow in the center of the die cast aluminum ORC housing is the electronic circuitry of the ORC which includes a microcontroller, electronic impact sensors and an energy storage capacitor. A stamped metal cover plate is secured to the bottom of the ORC housing with five screws to enclose and protect the internal electronic circuitry and components.

An arrow printed on the label (2) on the top of the ORC housing provides a visual verification of the proper orientation of the unit, and should always be pointed toward the front of the vehicle. The ORC housing has three integral mounting tabs and two integral locating pins. The molded plastic electrical connector (3), with two receptacles containing numerous terminal pins, exits the rearward facing side of the ORC housing. These terminal pins connect the ORC to the vehicle electrical system through two dedicated take outs and connectors, one from the body wire harness and one from the instrument panel wire harness.



The impact sensors internal to the ORC are calibrated for the specific vehicle, and are only serviced as a unit with the ORC. In addition, there are unique versions of the ORC for vehicles with or without side curtain airbags or seat (thorax) airbags, with or without third row seating as well as for those vehicles with domestic or export applications. These variations are necessary for both equipment needs and for compliance with certain regulatory requirements. The ORC cannot be repaired or adjusted and, if damaged or ineffective, it must be replaced.

INSTALLATION

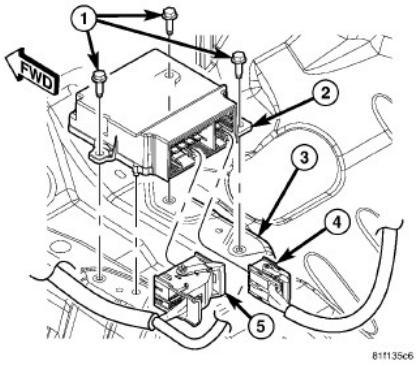
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with side curtain airbags, disable the Supplemental Restraint System (SRS) before attempting any Occupant Restraint Controller (ORC) diagnosis or service. The ORC may contain a rollover sensor, which enables the system to deploy the side SRS components in the event of a vehicle rollover event. If an ORC containing a rollover sensor is accidentally rolled during service while still connected to battery power, the side SRS components will deploy. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

WARNING: **To avoid serious or fatal injury, never strike or drop the Occupant Restraint Controller (ORC), as it can damage the impact sensor or affect its calibration. The ORC contains the impact sensor, which enables the system to deploy the Supplemental Restraint System (SRS) components. If an ORC is accidentally dropped during service, the module must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper SRS component deployment.**

1. Carefully position the Occupant Restraint Controller (ORC) (2) to the ORC bracket that is welded onto the top of the floor panel transmission tunnel. When the ORC is correctly positioned, the arrow on the ORC label will be pointed forward in the vehicle and the locating pins on the bottom of the ORC will be engaged into the locating holes in the ORC bracket.
2. Install and tighten the three screws (1) that secure the ORC to the ORC bracket. Tighten the screws to 12.5 N·m (9 ft. lbs.).



CAUTION: **The lever arms of the wire harness connectors for the ORC MUST be in the unlatched position before they are inserted into their connector receptacles on the ORC or they may become damaged.**

3. First reconnect the body wire harness connector (5), followed by the instrument panel wire harness connector (4) to the ORC connector receptacles located on the rearward facing side of the module. Be certain that the latches on both connectors are each fully engaged.
4. Reinstall the mini console onto the top of the floor panel transmission tunnel. (Refer to 23 - Body/Instrument Panel/BIN, Instrument Panel - Installation) .
5. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

NOTE: Service replacement ORC modules are shipped in a LOCKED OUT state and after installed will set a ORC UNLOCKED - ALL DEPLOYMENT DISABLED fault. Use a diagnostic scan tool to access the ORC module and go to the MISCELLANEOUS FUNCTIONS menu item to perform the MODULE INITIALIZATION procedure to erase the fault and initialize the new replacement ORC.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The microcontroller within the Occupant Restraint Controller (ORC) contains the Supplemental Restraint System (SRS) logic circuits and controls all of the SRS components. The ORC uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool using the Controller Area Network (CAN) data bus. This method of communication is used for control of the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and for SRS diagnosis and testing through the 16-way data link connector located on the driver side lower edge of the instrument panel.

The ORC microcontroller continuously monitors all of the SRS electrical circuits to determine the system readiness. If the ORC detects a monitored system fault, it sets an active and stored Diagnostic Trouble Code (DTC) and sends electronic messages to the IC over the CAN data bus to turn ON the airbag indicator. An active fault only remains for the duration of the fault, or in some cases for the duration of the current ignition cycle, while a stored fault causes a DTC to be stored in memory by the ORC. For some DTCs, if a fault does not recur for a number of ignition cycles, the ORC will automatically erase the stored DTC. For other internal faults, the stored DTC is latched forever.

The ORC receives battery current through two circuits; a fused ignition switch output (run) circuit through a fuse in the Body Control Module (BCM) (also known as the Common Body Controller/CBC) and a fused ignition switch output (run-start) circuit through a second fuse in the BCM. The ORC receives ground through a ground circuit and take out of the instrument panel wire harness that is secured by a ground screw to the body sheet metal. These connections allow the ORC to be operational whenever the ignition switch is in the START or ON positions.

The ORC also contains an energy-storage capacitor. When the ignition switch is in the START or ON positions, this capacitor is continually being charged with enough electrical energy to deploy the SRS components for up to one second following a battery disconnect or failure. The purpose of the capacitor is to provide backup SRS protection in case there is a loss of battery current supply to the ORC during an impact.

Various sensors within the ORC are continuously monitored by the ORC logic. These internal sensors, along with several external impact sensor inputs allow the ORC to determine both the severity of an impact and to verify the necessity for deployment of any SRS components. Two remote front impact sensors are located on the back of the right and left ends of the Front End Module (FEM) carrier inboard of the headlamps near the front of the vehicle. The electronic impact sensors are accelerometers that sense the rate of vehicle deceleration, which provides verification of the direction and severity of an impact.

The ORC also monitors inputs from an internal rollover sensor, a seat track position sensor, a seat belt switch and up to eight additional remote side impact sensors located on the left and right front door module carriers, on the right and left lower B and C-pillars and, on vehicles equipped with optional third row seating, on the right and left quarter inner panels to control deployment of the side curtain airbag units and seat (thorax) airbags.

The impact sensors within the ORC are electronic accelerometer sensors that provide an additional logic input to the ORC microcontroller. These sensors are used to verify the need for a SRS component deployment by detecting impact energy of a lesser magnitude than that of the primary electronic impact sensors, and must exceed a safing threshold in order for the SRS components to deploy. On vehicles equipped with side curtain airbags or seat airbags, a separate impact sensor within the ORC provides confirmation to the ORC microcontroller of side impact forces. This separate sensor is a bi-directional unit that detects impact forces from either side of the vehicle.

Pre-programmed decision algorithms in the ORC microcontroller determine when the deceleration rate as signaled by the impact sensors indicate an impact that is severe enough to require SRS protection and, based upon the severity of the monitored impact, determines the level of front airbag deployment force required for each front seating position. When the programmed conditions are met, the ORC sends the proper electrical signals to deploy the dual multistage front airbags at the programmed force levels, the Passenger AirBag (PAB) active vent tether cutter, the front seat belt tensioners, the Active Head Restraint (AHR) units and either side curtain or seat airbag unit.

The hard wired inputs and outputs for the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the ORC or the electronic controls and communication between other modules and devices that provide some features of the SRS. The most reliable, efficient and accurate means to diagnose the ORC or the electronic controls and communication related to SRS operation requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

ACTIVE RESTRAINTS

The primary passenger restraints in this or any other vehicle are the standard equipment factory-installed seat belts and child restraint anchors. Seat belts and child restraint anchors are referred to as an active restraint because the vehicle occupants are required to physically fasten and properly adjust these restraints in order to benefit from them.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

PASSIVE RESTRAINTS

The passive restraints are referred to as Supplemental Restraint System (SRS) components because they were designed and are intended to enhance the protection for the occupants of the vehicle **only** when used in conjunction with the seat belts. They are referred to as passive restraints because the vehicle occupants are not required to do anything to make them operate; however, the vehicle occupants must be wearing their seat belts in order to obtain the maximum safety benefit from the factory-installed SRS components. In addition, each front seat occupant must have their Active Head Restraint (AHR) unit properly adjusted in order to obtain its maximum safety benefit.

The SRS electrical circuits are continuously monitored and controlled by a microcontroller and software contained within the Occupant Restraint Controller (ORC). An airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) illuminates from four to six seconds as a bulb test each time the status of the ignition switch transitions to On or Start. Following the bulb test, the airbag indicator is turned On or Off by the ORC to indicate the status of the SRS. If the airbag indicator comes On at any time other than during the bulb test, it indicates that there is a problem in the SRS electrical circuits. Such a problem may cause airbags not to deploy when required, or to deploy when not required.

Deployment of the SRS components depends upon the angle and severity of an impact. Deployment is not based upon vehicle speed; rather, deployment is based upon the rate of deceleration as measured by the forces of gravity (G force) upon the acceleration-type impact sensors, or by a pressure wave within a front door as measured by the pressure-type impact sensor. When an impact is severe enough, the microcontroller within the ORC signals the inflator of the appropriate airbag units to deploy their airbag cushions.

The front seat belt retractor tensioners and, if equipped, the Knee AirBag (KAB) (also known as the Inflatable Knee Blocker/IKB) are provided with a deployment signal by the ORC in conjunction with the front airbags. The side curtain airbags (also known as the Side AirBag Inflatable Curtains/SABIC) and, on vehicles so equipped, the Seat AirBags (SAB) (also known as pelvic and thoracic airbags) are provided with a deployment signal individually by the ORC based upon a side impact sensor input for the same side of the vehicle. The ORC also contains a rollover sensor. Should the vehicle roll over and not cause any acceleration-type or pressure-type impact sensor to signal the need for a deployment, the rollover sensor in the ORC will deploy the side curtain air bags, the SAB units and under certain conditions, will also actuate the seat belt retractor tensioners.

The two AHR units are provided with a simultaneous deployment signal by the ORC independent from any of the other passive restraints only as a result of an impact pulse originating at the rear of the vehicle, but will not deploy with the transmission gear selector in the Reverse **(R)** position.

During a frontal vehicle impact, the static knee blockers work in concert with properly fastened and adjusted seat belts to restrain both the driver and the front seat passenger in the proper position for an airbag deployment. The knee blockers also absorb and distribute the crash energy from the driver and the front seat passenger to the structure of the instrument panel. The seat belt tensioners remove the slack from the front seat belts to provide further assurance that the driver and front seat passenger are properly positioned and restrained for an airbag deployment.

Typically, the vehicle occupants recall more about the events preceding and following a collision than they do of an airbag deployment itself. This is because the airbag deployment and deflation occur very rapidly. In a typical 48 kilometer-per-hour (30 mile-per-hour) barrier impact, from the moment of impact until the airbags are fully inflated takes about 40 milliseconds. Within one to two seconds from the moment of impact, the airbags are almost entirely deflated. The times cited for these events are approximations, which apply only to a barrier impact at the given speed. Actual times will vary somewhat, depending upon the vehicle speed, impact angle, severity of the impact, and the type of collision.

When the ORC monitors a problem in any of the SRS circuits or components, including the seat belt tensioners and AHR units, it stores a fault code or Diagnostic Trouble Code (DTC) in its memory circuit and sends an electronic message to the IC to turn On the airbag indicator. The hard wired circuits between components related to the SRS may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the SRS or the electronic controls and communication between other modules and devices that provide features of the SRS. The most reliable, efficient and accurate means to diagnose the SRS or the electronic controls and communication related to SRS operation, as well as the retrieval or erasure of a DTC requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

PEDESTRIAN PROTECTION SYSTEM

In the event of a frontal vehicle impact, the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System) components are designed and intended to enhance the protection for pedestrians from the hard components found just beneath the hood of the vehicle within the engine compartment. The EPP system has three primary acceleration-type impact sensors located in the front bumper area of the vehicle, two additional acceleration-type safing sensors located on the back of the front bumper fascia, a microcontroller-based Electronic Pedestrian Protection Module (EPPM) located within the passenger compartment of the vehicle and an active hood hinge with a pyrotechnic-type actuator at each rear corner of the hood panel.

The impact sensors and safing sensors continually transmit sensor data to the EPPM that give an indication of the forces of gravity (G force) upon the sensors. The two outboard impact sensors are each connected in a daisy chain to the EPPM through the adjacent right or left safing sensor, while the center impact sensor provides a direct input to the EPPM. The EPPM also receives electronic message inputs over the Controller Area Network (CAN) data bus indicating the ignition status, vehicle speed and ambient temperature.

If the vehicle has a collision, the EPPM uses algorithms to analyze all of the input data to determine whether to deploy the hood. If the algorithm makes a deployment decision and the vehicle speed is between 22 kilometers-per-hour (14 miles-per-hour) and 52 kilometers-per-hour (32 miles-per-hour), then the EPPM will send electrical signals to deploy the actuators on the active hood hinges.

When the Micro Gas Generator (MGG) in each actuator is energized, it produces a large quantity of expanding gas. The expanding gas moves a piston within the actuator that pushes upward against the hood bracket of the active hood hinge. The force of the actuator on the hinge bracket creates a lever action that shears a rivet between the hood bracket and the mid-strap of both hood hinges, allowing the actuators to lift the rear of the hood at the hinges. Lifting the rear of the hood in this manner provides additional clearance between the hood and the hard components found within the engine compartment.

Each active hood hinge functions normally during routine opening and closing of the hood. However, upon active hood hinge deployment the rear of the hood is lifted to a predetermined height, which is controlled by an up-stop pin on the mid-strap that is engaged within a slotted hole in the hood bracket of each hinge.

During a frontal pedestrian impact, the purpose of the front energy absorber foam material and the pedestrian bar (also known as the leg catcher) that supports the lower front fascia is to reduce the severity of leg injuries and to position the pedestrian onto the hood of the vehicle rather than onto the pavement. These goals are intended to reduce both the severity and the debilitating nature of potential pedestrian injuries. It should be noted that the front energy absorber foam material and the pedestrian bar **must** be inspected and replaced if visually damaged following **any** frontal vehicle impact, regardless of whether a pedestrian is involved.

The EPP system electrical circuits are continuously monitored and controlled by the EPPM microcontroller. If the EPPM detects a problem it stores a fault code or Diagnostic Trouble Code (DTC) in its memory circuit. The Occupant Restraint Controller (ORC) continually monitors the EPPM. If the ORC detects that the EPPM has stored a DTC, the ORC responds by sending an electronic request message to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) to illuminate the airbag indicator. The airbag indicator may be turned On or Off by the ORC to indicate a problem in either the Supplemental Restraint System (SRS) or the EPP system electrical circuits.

The hard wired circuits between components related to the EPP system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the EPP system or the electronic controls and communication between other modules and devices that provide inputs to the EPPM. The most reliable, efficient and accurate means to diagnose the EPPM or the electronic controls and communication related to EPP system operation, as well as the retrieval or erasure of a DTC requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

SUPPLEMENTAL RESTRAINT SYSTEM

The Supplemental Restraint System (SRS) is comprised of two primary subsystems: Active Restraints and Passive Restraints. In addition, vehicles manufactured for certain export markets include the Electronic Pedestrian Protection (EPP) system (also known as the PedPro or the Active Hood System), which includes both dynamic and static elements designed to enhance the protection of pedestrians. Additional operational details on each of these subsystems of the SRS can be found elsewhere within this service information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Electronic Pedestrian Protection (EPP) safing sensors (2) are found only in vehicles equipped with the EPP system (also known as the PedPro or Active Hood System), which is available only in vehicles manufactured for certain export markets. These sensors are mounted at the front of the vehicle to provide a redundant logic input for use by the Electronic Pedestrian Protection Module (EPPM) to confirm inputs from the two outboard EPP impact sensors.

The EPP safing sensors are satellite acceleration-type sensors that are mounted to the inner surface of the front bumper fascia at the front of the vehicle. The two safing sensors are each secured by a nut to a weld stud within a dedicated bracket located just inboard of each front fog lamp on the inside of the front bumper fascia.

Each sensor housing (1) has an integral 4 pin connector receptacle (4), an integral locator pin (3) and an integral mounting hole with a metal sleeve (2) to provide crush protection. A cavity in the center of the molded plastic safing sensor housing contains the electronic circuitry of the sensor which includes an electronic communication chip and an electronic acceleration sensor. Potting material fills the cavity and a translucent molded cover is laser welded over the cavity to seal and protect the internal electronic circuitry and components.

The EPP safing sensors are each connected to the vehicle electrical system through dedicated take outs and connectors of the headlamp and dash wire harness. These acceleration-type safing sensors cannot be repaired or adjusted and, if damaged or ineffective, they must be replaced.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

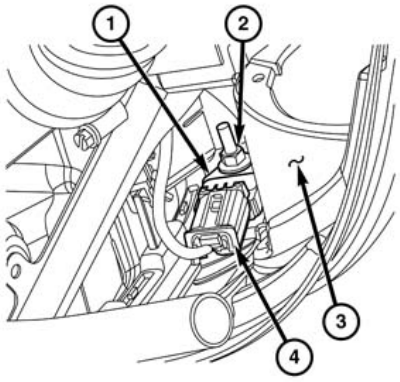
To avoid serious or fatal injury on vehicles equipped with the Electronic Pedestrian Protection (EPP) system, disable the system before attempting any EPP system component diagnosis or service. With the ignition switch in the OFF position, disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the EPP system. Failure to take the proper precautions could result in accidental active hood hinge actuator deployment.

WARNING:

To avoid serious or fatal injury, never strike or drop the Electronic Pedestrian Protection (EPP) system impact sensor, as it can damage the impact sensor or affect its calibration. The EPP impact sensor enables the system to deploy the EPP system active hood hinge actuators. If an impact sensor is accidentally dropped during service, the sensor must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper EPP active hood hinge actuator deployment.

NOTE:

The following procedure is for replacement of an ineffective or damaged Electronic Pedestrian Protection (EPP) system safing sensor. Whether the EPP system has been deployed or the vehicle has had a front end collision without EPP system deployment, review the recommended procedures for Service After A Pedestrian Protection Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



0831010867

1. Carefully position the right or left Electronic Pedestrian Protection (EPP) safing sensor (1) onto the stud within the bracket on the back of the front fascia just inboard of the front fog lamp opening (3). Be certain that the anti-rotation pin on the back of the sensor is engaged in the clearance hole of the bracket.
2. Install and tighten the nut (2) that secures the sensor to the stud. Tighten the nut to 8 N·m (70 in. lbs.).
3. Reconnect the headlamp and dash wire harness connector (4) to the right or left EPP safing sensor connector receptacle.
4. Reinstall the front fascia lower closeout onto the vehicle. (Refer to 13 - Frame and Bumpers/Bumpers/FASCIA, Front Lower, Closeout/Installation) .
5. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any EPP component. (Refer to 10 - Restraints - Standard Procedure) .

OPERATION

The acceleration-type Electronic Pedestrian Protection (EPP) safing sensors are electronic accelerometers that sense the rate of vehicle deceleration, which provides a redundant verification of the direction and severity of an impact sensed by the EPP impact sensors. Each sensor also contains an electronic communication chip that allows the unit to communicate the sensor status as well as sensor fault information to the microcontroller within the Electronic Pedestrian Protection Module (EPPM).

The EPPM microcontroller continuously monitors all of the EPP system electrical circuits to determine the system readiness. If the EPPM detects a monitored system fault, it sets a Diagnostic Trouble Code (DTC). The ORC continually monitors the EPPM and, when it detects that the EPPM has logged a DTC, it sends electronic request messages over the CAN data bus to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) to turn On the airbag indicator. The EPPM also stores a DTC after the fault has been resolved. The safing sensors each receive battery current and ground through the dedicated left and right safing sensor plus and minus circuits from the EPPM. The safing sensors and the EPPM communicate by modulating the voltage in the sensor plus circuit.

The hard wired circuits between the acceleration-type EPP safing sensors and the EPPM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the safing sensors or the electronic controls and communication between other modules and devices that provide features of the EPP system. The most reliable, efficient and accurate means to diagnose the safing sensors or the electronic controls and communication related to acceleration-type EPP safing sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

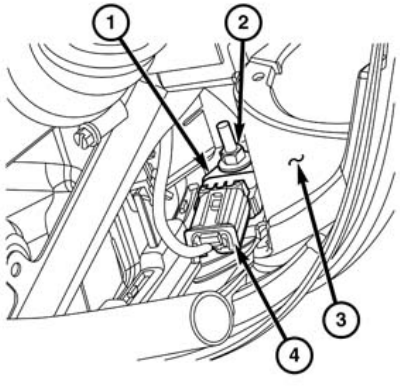
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with the Electronic Pedestrian Protection (EPP) system, disable the system before attempting any EPP system component diagnosis or service. With the ignition switch in the OFF position, disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the EPP system. Failure to take the proper precautions could result in accidental active hood hinge actuator deployment.**

WARNING: **To avoid serious or fatal injury, never strike or drop the Electronic Pedestrian Protection (EPP) system impact sensor, as it can damage the impact sensor or affect its calibration. The EPP impact sensor enables the system to deploy the EPP system active hood hinge actuators. If an impact sensor is accidentally dropped during service, the sensor must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper EPP active hood hinge actuator deployment.**

NOTE: The following procedure is for replacement of an ineffective or damaged Electronic Pedestrian Protection (EPP) system safing sensor. Whether the EPP system has been deployed or the vehicle has had a front end collision without EPP system deployment, review the recommended procedures for Service After A Pedestrian Protection Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



0831010867

1. With the status of the ignition switch Off, disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Partially remove the front fascia lower closeout from the vehicle. (Refer to 13 - Frame and Bumpers/Bumpers/FASCIA, Front Lower, Closeout/Removal) .
3. Locate the left or right Electronic Pedestrian Protection (EPP) safing sensor (1) on the back of the front fascia just inboard of the front fog lamp opening (3).
4. Disconnect the headlamp and dash wire harness connector (4) from the right or left EPP safing sensor connector receptacle.
5. Remove the nut (2) that secures the EPP safing sensor to the stud within the bracket on the back of the front fascia.
6. Remove the right or left EPP safing sensor from the front fascia.

FRONT

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Position the front seat belt buckle (1) lower anchor to the bracket at the back of the inboard seat track.
2. Install and tighten the screw (3) that secures the lower anchor to the seat track bracket. Tighten the screw to 39 N·m (29 ft. lbs.).
3. Reinstall the front seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .
4. Reconnect the negative cable to the battery.

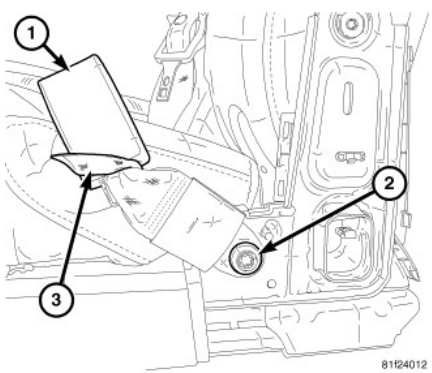
SECOND ROW - CENTER

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Engage the second row center seat belt buckle (1) through the elastic loop (3) of the right seat cushion trim cover.
2. Position the buckle lower anchor to the left rear corner of the right seat frame.
3. Install and tighten the screw (2) that secures the buckle unit to the right seat frame. Tighten the screw to 39 N·m (29 ft. lbs.).



4. Position the outboard center seat back hinge bracket outboard trim (2) over the buckle (1) anchor on the left rear corner of the right seat frame.
5. Using hand pressure, align and press the outboard center seat back hinge bracket outboard trim toward the hinge bracket until the snap clip that secures the center of the trim snaps into the bracket.
6. Using hand pressure, squeeze the edges of the outboard center seat back hinge bracket outboard and inboard trim halves together until the four integral latch features that secure the two halves of the trim to each other are fully engaged.
7. Install the plastic push-in fastener (3) that secures the outboard center seat back hinge bracket outboard trim over the buckle anchor.
8. Restore the second row left seat to the fully rearward position.

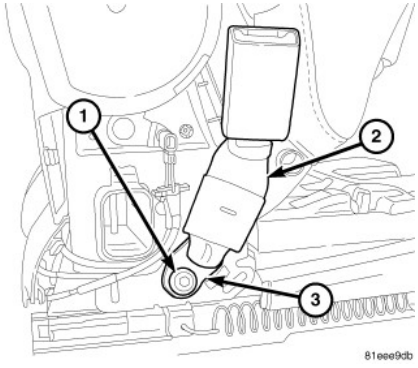
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Engage the second row left seat belt buckle through the elastic loop (2) of the left seat cushion trim cover.
2. Position the buckle lower anchor (3) to the right rear corner of the left seat frame.
3. Install and tighten the screw (1) that secures the buckle unit to the left seat frame. Tighten the screw to 39 N·m (29 ft. lbs.).



4. Position the trim (2) over the buckle (3) anchor on the right rear corner of the left seat frame.
5. Install and tighten the screw (1) that secures the trim over the buckle anchor. Tighten the screw securely.
6. Restore the second row right seat to the fully rearward position.

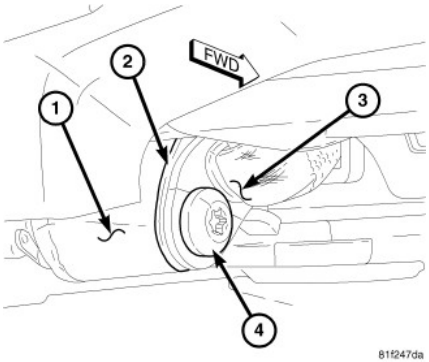
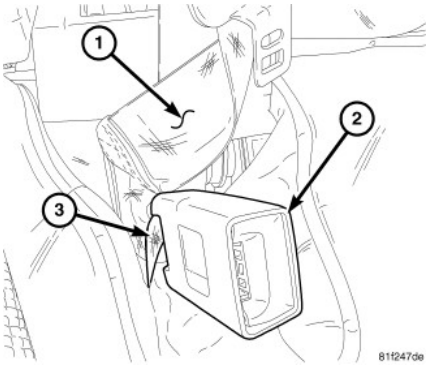
1. Move the second row right seat to the fully forward position.
2. Reach under the rear edge of the second row right seat cushion frame just to the right of the lower end of the inboard center seat back hinge bracket (1) to access the right buckle lower anchor (3) and the center seat belt lower anchor (2).
3. Remove the screw (4) that secures the right buckle lower anchor and the center seat belt lower anchor to the right seat cushion frame.



4. From the front of the second row right seat, disengage the buckle (2) from the elastic loop (3) of the right seat cushion trim cover and pull the buckle lower anchor out from between the right seat cushion and back trim covers.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The seat belt retractors used in all seating positions include an inertia-type, emergency locking mechanism as standard equipment. However, the retractor locking mechanism for all seating positions except the driver side front and the second row center are mechanically switchable from an emergency locking retractor to an automatic locking retractor. The primary function of this feature is to securely accommodate a child seat in these seating positions of the vehicle without the need for a self-cinching seat belt tip half latch plate unit or another supplemental device that would be required to prevent the seat belt webbing from unwinding freely from the retractor spool of an inertia-type emergency locking retractor mechanism.

The automatic locking mechanism is integral to the seat belt retractor unit and is concealed beneath a molded plastic cover located on the side of the retractor spool. The automatic locking mechanism cannot be adjusted or repaired and, if ineffective or damaged, the entire seat belt and retractor unit must be replaced.

FRONT

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

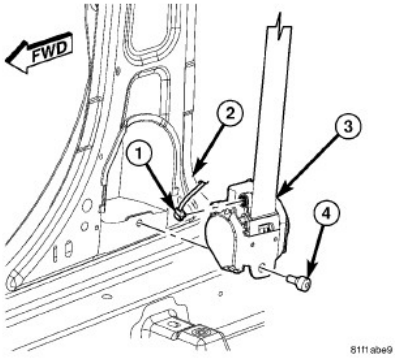
To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

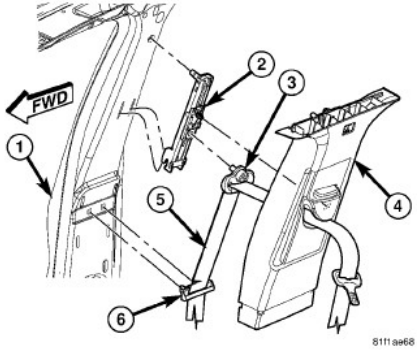
NOTE:

The following procedure is for replacement of an ineffective or damaged seat belt and retractor unit. The front retractor also includes a seat belt tensioner. If the front seat belt or retractor is ineffective or damaged, but the seat belt tensioner is not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the seat belt tensioner has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



1. Position the front seat belt and retractor (3) to the inner B-pillar (2) as a unit.
2. On the driver side only, reconnect the body wire harness connector to the seat belt switch connector receptacle on the retractor.
3. Reconnect the body wire harness connector (1) to the seat belt tensioner initiator on the retractor.
4. Install and tighten the screw (4) that secures the lower retractor bracket to the inner B-pillar. Tighten the screw to 58 N·m (43 ft. lbs.).
5. Be certain to route the wiring for the seat belt tensioner behind the B-pillar flange to ensure it does not interfere with the seat belt webbing.
6. Position the web guide (6) to the B-pillar (1). Be certain the seat belt webbing (5) is not twisted between the retractor and the web guide.
7. Using hand pressure, press firmly and evenly on the web guide to snap it into place.
8. Position the seat belt turning loop onto the height adjuster (2) on the upper B-pillar. Be certain the seat belt webbing is not twisted between the web guide and the turning loop.
9. Install and tighten the screw (3) that secures the turning loop to the height adjuster. Tighten the screw to 37 N·m (27 ft. lbs.).

10. Reinstall the upper (4) and lower trim onto the B-pillar. (Refer to 23 - Body/Interior /PANEL, B-Pillar Trim - Installation) .



11. Position the front seat belt (1) lower anchor to the bracket on the outboard side of the front seat (2) cushion frame. Be certain the seat belt webbing is not twisted between the turning loop and the lower anchor.

12. Install and tighten the screw (4) that secures the lower anchor to the bracket on the outboard side of the front seat cushion frame. Tighten the screw to 51 N·m (38 ft. lbs.).

13. Align the seat belt anchor cover (3) to the opening near the rear of the outboard seat side shield. Using hand pressure, press firmly and evenly on the cover until it snaps into place.

14. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. (Refer to 10 - Restraints - Standard Procedure) .

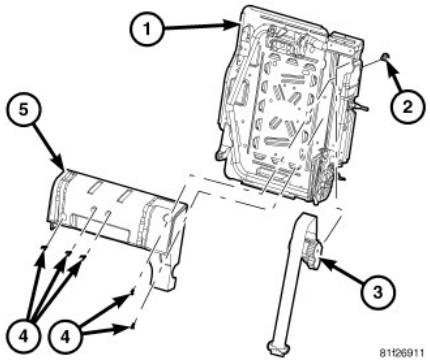
SECOND ROW - CENTER

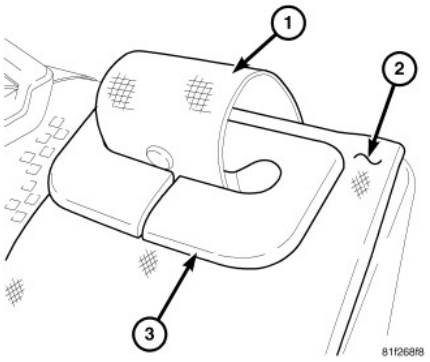
Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.



1. Guide the seat belt webbing through the slot in the top of the right seat back frame (1) while positioning the center seat belt and retractor (3) to the frame as a unit. Be certain the seat belt webbing is not twisted between the retractor and the top of the seat.
2. Engage the T-tab of the retractor bracket with the keyed slot in the seat back frame.
3. From the back side of the seat back frame, install and tighten the screw (2) that secures the retractor to the frame. Tighten the screw to 39 N·m (29 ft. lbs.).
4. Position the molded plastic shield (5) onto the top of the seat back frame.
5. Install and tighten the screws (4) that secure the molded plastic shield to the top of the seat back frame. Pull the top of the seat back foam away from the seat back frame to access the lower screws securing the shield.
6. Reinstall the trim cover, back panel and head rest to the right seat back frame. (Refer to 23 - Body/Seats/SEAT BACK - Installation) .



7. Grasp the center seat belt webbing (1) between where it exits the top of the seat and the seat belt latch plate and slide it through the slot in the belt web guide bezel (3) to engage the belt through the bezel.
8. Position the guide bezel to the top of the right seat back (2) with the slot facing forward.
9. Using hand pressure, press the guide bezel down onto the top of the right seat back far enough to engage the three barrel clips that secure the bezel to the seat back frame.
10. From the front of the second row right seat, insert the center seat belt lower anchor between the right seat cushion and back trim covers. Be certain the seat belt webbing is not twisted between the top of the seat and the belt lower anchor.
11. Reach under the rear edge of the second row right seat cushion frame just to the right of the lower end of the inboard center seat back hinge bracket (1) to position the buckle lower anchor (3) and the center seat belt lower anchor (2) to the right seat frame.
12. Install and tighten the screw (4) that secures the buckle unit and the center seat belt lower anchor to the right seat frame. Tighten the screw to 39 N·m (29 ft. lbs.).

13. Reinstall the second row right seat into the vehicle. (Refer to 23 - Body/Seats/SEAT - Installation) .

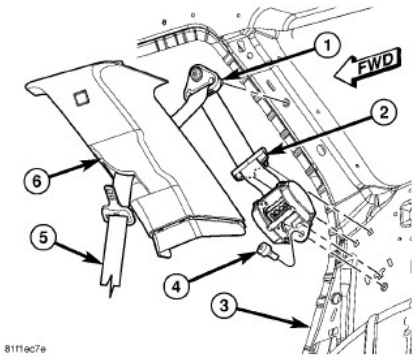
SECOND ROW - OUTBOARD

Labor Operations: Click to display a list of Labor Operations associated with this procedure

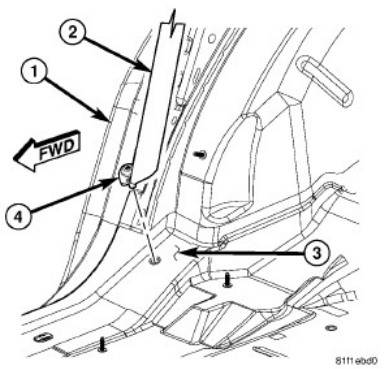
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Position the second row outbound seat belt and retractor (5) to the quarter inner panel just below the base of the upper C-pillar (3) as a unit.
2. Engage the tab on the retractor bracket into the keyed hole in the quarter inner panel.
3. Install and tighten the screw (4) that secures the retractor to the quarter inner panel. Tighten the screw to 58 N·m (43 ft. lbs.).
4. Position the web guide (2) to the quarter inner panel near the base of the C-pillar. Be certain the seat belt webbing is not twisted between the retractor and the web guide.



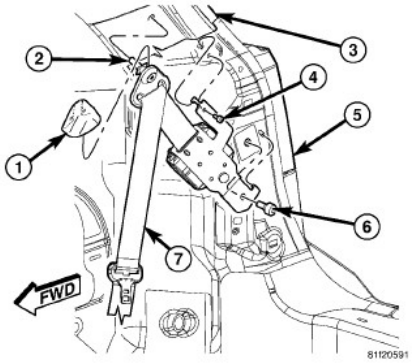
5. Using hand pressure, press firmly and evenly on the web guide to snap it into place.
6. Position the seat belt turning loop to the inside of the upper C-pillar. Be certain the seat belt webbing is not twisted between the web guide and the turning loop.
7. Install and tighten the screw (1) that secures the turning loop to the C-pillar. Tighten the screw to 43 N·m (32 ft. lbs.).
8. Reinstall the upper trim (2) onto the inside of the C-pillar (5). (Refer to 23 - Body/Interior/PANEL, C-Pillar Trim - Installation) .
9. Position the lower seat belt (2) anchor to the rear floor panel (3) near the base of the lower C-pillar (1). Be certain the seat belt webbing is not twisted between the turning loop and the lower anchor.
10. Install and tighten the screw (4) that secures the lower seat belt anchor to the floor. Tighten the screw to 58 N·m (43 ft. lbs.).
11. Reinstall the front of the quarter trim panel onto the lower C-pillar. (Refer to 23 - Body/Interior /PANEL, Quarter Trim - Installation) .



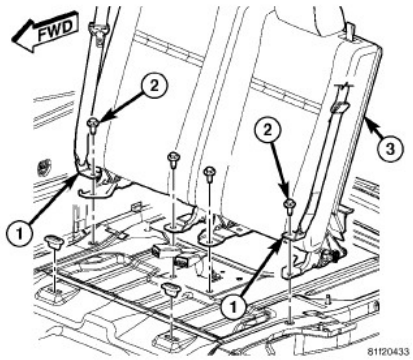
THIRD ROW SEAT BELT AND RETRACTOR

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.**



1. Position the third row seat belt and retractor (7) to the inside of the D-pillar (5) as a unit.
2. Engage the tab of the upper retractor bracket into the keyed hole in the D-pillar.
3. Install and tighten the screw (6) that secures the lower retractor bracket to the inside of the D-pillar. Tighten the screw to 58 N·m (43 ft. lbs.).
4. Install and tighten the screw (4) that secures the upper retractor bracket to the inside of the D-pillar. Tighten the screw to 10 N·m (7 ft. lbs.).
5. Reinstall the rear of the quarter trim panel to the lower D-pillar (Refer to 23 - Body/Interior /PANEL, Quarter Trim - Installation) .
6. Reinstall the trim (3) onto the inside of the upper D-pillar (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Installation) .
7. Position the seat belt turning loop to the inside of the upper D-pillar. Be certain the seat belt webbing (5) is not twisted between the retractor and the turning loop.
8. Install and tighten the screw (2) that secures the turning loop to the bracket on the inside of the upper D-pillar. Tighten the screw to 43 N·m (32 ft. lbs.).
9. Snap the trim cover (1) over the seat belt turning loop on the inside of the upper D-pillar.



10. Position the seat belt lower anchor (1) to the third row seat back (3) outboard bracket on the rear floor panel. Be certain the seat belt webbing is not twisted between the turning loop and the lower anchor.
11. Install and tighten the screw (2) that secures the lower anchor and the third row seat back outboard bracket to the rear floor panel. Tighten the screw to 90 N·m (66 ft. lbs.).
12. Reinstall the third row seat cushion and cover to the rear floor panel (Refer to 23 - Body/Seats/COVER, Seat Cushion - Installation) .

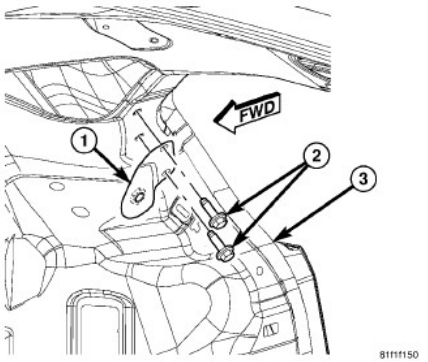
THIRD ROW TURNING LOOP BRACKET

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Position the third row turning loop bracket (1) to the inside of the upper D-pillar (3).
2. Install and tighten the two screws (2) that secure the turning loop bracket to the D-pillar. Tighten the screws to 22 N·m (16 ft. lbs.).



3. Reinstall the trim (3) onto the inside of the upper D-pillar. (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Installation) .
4. Position the seat belt turning loop to the inside of the upper D-pillar. Be certain the seat belt webbing (5) is not twisted between the retractor and the turning loop as well as between the turning loop and the lower anchor.
5. Install and tighten the screw (2) that secures the turning loop to the bracket on the inside of the upper D-pillar. Tighten the screw to 43 N·m (32 ft. lbs.).
6. Snap the trim cover (1) over the seat belt turning loop on the inside of the upper D-pillar.

OPERATION

The locked mode of the retractor is engaged and the automatic locking retractor is switched from operating as a standard inertia-type emergency locking retractor by first buckling the combination lap and shoulder belt buckle. Then grasp the shoulder belt and pull all of the webbing out of the retractor. Once all of the belt webbing is extracted from the spool, the retractor will automatically become engaged in the pre-locked automatic locking mode and will make an audible clicking or ratchet-like sound as the shoulder belt is allowed to retract to confirm that the automatic locking mode is now engaged. Once the automatic locking mode is engaged, the retractor will remain locked and the belt will remain tight around whatever it is restraining.

The retractor is returned to standard emergency locking (inertia) mode by unbuckling the combination lap and shoulder belt buckle and allowing the belt webbing to be almost fully retracted onto the retractor spool. The emergency locking mode is confirmed by the absence of the audible clicking or ratchet-like sound as the belt webbing retracts. This mode will allow the belt to unwind from and wind onto the retractor spool freely unless and until a predetermined inertia load is sensed, or until the retractor is again switched to the automatic locking mode.

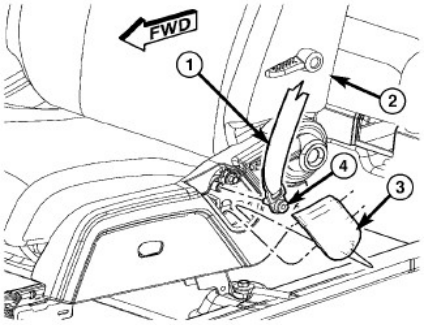
FRONT

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

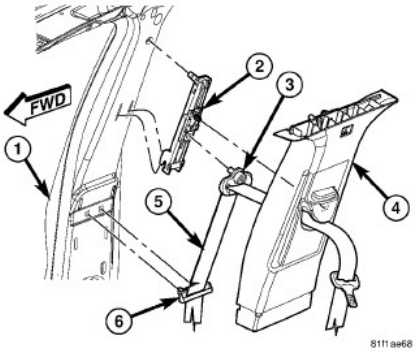
WARNING: **To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.**

NOTE: The following procedure is for replacement of an ineffective or damaged seat belt and retractor unit. The front retractor also includes a seat belt tensioner. If the front seat belt or retractor is ineffective or damaged, but the seat belt tensioner is not deployed, review the recommended procedures for Handling Non-Deployed Supplemental Restraints. (Refer to 10 - Restraints - Standard Procedure) . If the seat belt tensioner has been deployed, review the recommended procedures for Service After A Supplemental Restraint Deployment before removing the unit from the vehicle. (Refer to 10 - Restraints - Standard Procedure) .



8111a4e7

1. Adjust the front seat to its most forward position for easiest access to the front seat belt lower anchor and the B-pillar trim.
2. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
3. Using a trim stick or another suitable wide flat-bladed tool, gently pry the seat belt anchor cover (3) to remove it from the rear of the outboard front seat (2) side shield.
4. Remove the screw (4) that secures the front seat belt (1) lower anchor to the bracket on the outboard side of the front seat cushion frame.
5. Remove the lower and upper trim (4) from the B-pillar (1). (Refer to 23 - Body/Interior /PANEL, B-Pillar Trim - Removal) .
6. Remove the screw (3) that secures the seat belt (5) turning loop to the height adjuster (2) on the upper B-pillar.
7. Using a trim stick or another suitable wide flat-bladed tool, gently pry the seat belt web guide (6) to unsnap it from the B-pillar.



8111ae68

8. Disconnect the body wire harness connector (1) from the seat belt tensioner initiator on the retractor (3).

9. On the driver side only, disconnect the second body wire harness connector from the seat belt switch connector receptacle on the retractor.

10. Remove the screw (4) that secures the lower retractor bracket to the inner B-pillar (2).

11. Remove the front seat belt and retractor from the B-pillar as a unit.

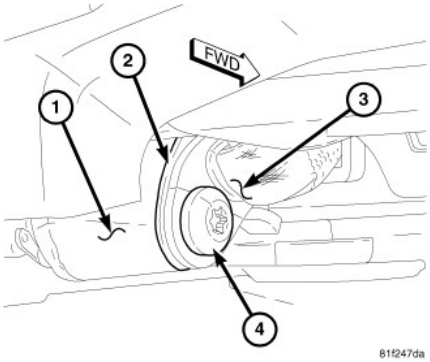
SECOND ROW - CENTER

Labor Operations: Click to display a list of Labor Operations associated with this procedure

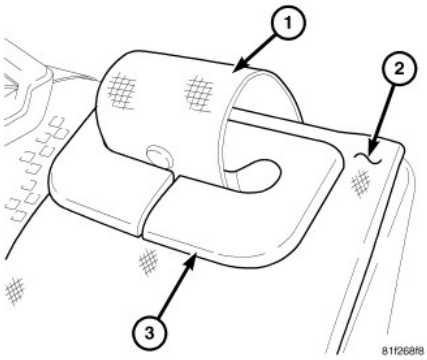
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

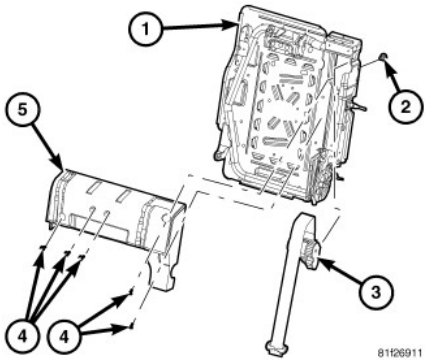
1. Remove the second row right seat from the vehicle. (Refer to 23 - Body/Seats/SEAT - Removal) .
2. Reach under the rear edge of the second row right seat cushion frame just to the right of the lower end of the inboard center seat back hinge bracket (1) to access the right buckle lower anchor (3) and the center seat belt lower anchor (2).
3. Remove the screw (4) that secures the right buckle lower anchor and the center seat belt lower anchor to the right seat cushion frame.
4. From the front of the second row right seat, pull the center seat belt lower anchor out from between the right seat cushion and back trim covers.



5. Using a trim stick or another suitable wide flat-bladed tool, carefully pry the belt web guide bezel (3) upward from the top of the right seat back (2) far enough to disengage the three barrel clips that secure the bezel to the seat back frame.
6. Slide the center seat belt webbing (1) through the slot in the guide bezel to disengage the belt from the bezel.



7. Remove the head rest, back panel and trim cover from the right seat back frame (1). It is not necessary to remove the seat back frame from the seat cushion frame. (Refer to 23 - Body/Seats/SEAT BACK - Removal) .
8. Remove the screws (4) that secure the molded plastic shield (5) to the top of the seat back frame. Pull the top of the seat back foam away from the seat back frame to access the lower screws securing the shield.
9. Remove the molded plastic shield from the top of the seat back frame.
10. From the back side of the seat back frame, remove the screw (2) that secures the retractor (3) to the frame.



11. Lift the retractor upward far enough to disengage the T-tab of the retractor bracket from the keyed slot in the seat back frame.

12. Guide the seat belt webbing through the slot in the top of the seat back frame while removing the seat belt and retractor from the seat as a unit.

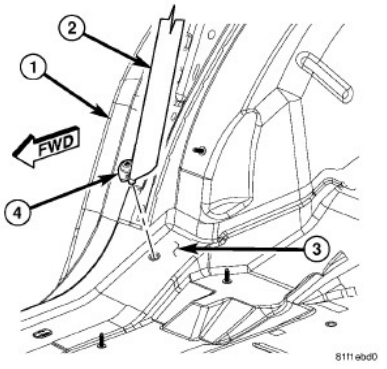
SECOND ROW - OUTBOARD

Labor Operations: Click to display a list of Labor Operations associated with this procedure

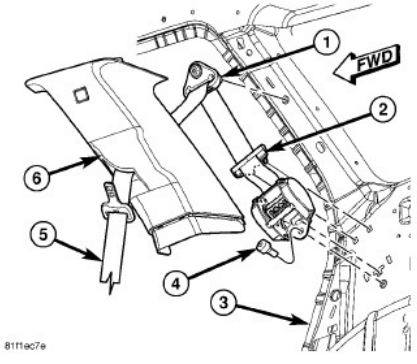
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Loosen the front of the quarter trim panel from the lower C-pillar (1) enough to access the second row outboard seat belt and retractor. (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Removal) .
2. Remove the screw (4) that secures the second row outboard seat belt (2) lower anchor to the rear floor panel (3) near the base of the C-pillar.



3. Remove the upper trim (6) from the inside of the C-pillar (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Removal) .
4. Remove the screw (1) that secures the seat belt turning loop to the inside of the upper C-pillar (3).
5. Remove the seat belt turning loop from the C-pillar.
6. Using a trim stick or another suitable wide flat-bladed tool, gently pry the seat belt web guide (2) to unsnap it from the quarter inner panel near the base of the C-pillar.



7. Remove the screw (4) that secures the retractor (5) bracket to the quarter inner panel.
8. Lift the retractor upward far enough to disengage the retractor tab from the keyed hole in the quarter inner panel.
9. Remove the second row outboard seat belt and retractor from the vehicle as a unit.

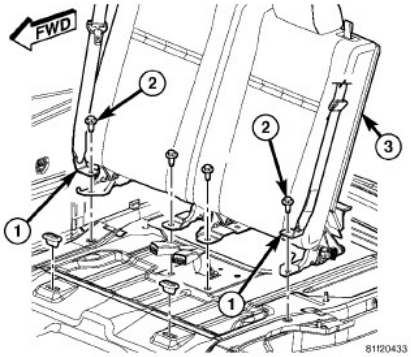
THIRD ROW SEAT BELT AND RETRACTOR

Labor Operations: Click to display a list of Labor Operations associated with this procedure

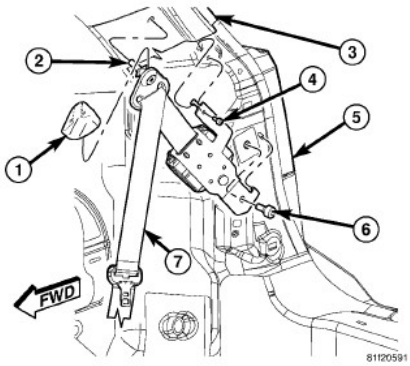
WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

1. Remove the third row seat cushion and cover from the rear floor panel (Refer to 23 - Body/Seats /COVER, Seat Cushion - Removal) .
2. Remove the screw (2) that secures the third row seat belt lower anchor (1) and the third row seat back (3) outboard bracket to the rear floor panel.
3. Remove the lower anchor from the third row seat back outboard bracket.



4. Pry between the back of the third row seat belt turning loop on the inside of the upper D-pillar trim (3) and the back of the trim cover (1) to unsnap and remove it for access to the turning loop screw (2).
5. Remove the screw (2) that secures the seat belt turning loop to the bracket on the inside of the upper D-pillar.
6. Remove the turning loop from the D-pillar.
7. Remove the trim from the inside of the upper D-pillar (Refer to 23 - Body/Interior/PANEL, D-Pillar Trim - Removal) .



8. Loosen the rear of the quarter trim panel from the lower D-pillar enough to access the third row outboard seat belt and retractor (7) (Refer to 23 - Body/Interior /PANEL, Quarter Trim - Removal) .
9. Remove the screw (4) that secures the upper retractor bracket to the inside of the D-pillar.
10. Remove the screw (6) that secures the lower retractor bracket to the inside of the D-pillar.
11. Lift the retractor upward far enough to disengage the tab of the upper retractor bracket from the keyed hole in the D-pillar.
12. Remove the third row seat belt and retractor from the vehicle as a unit.

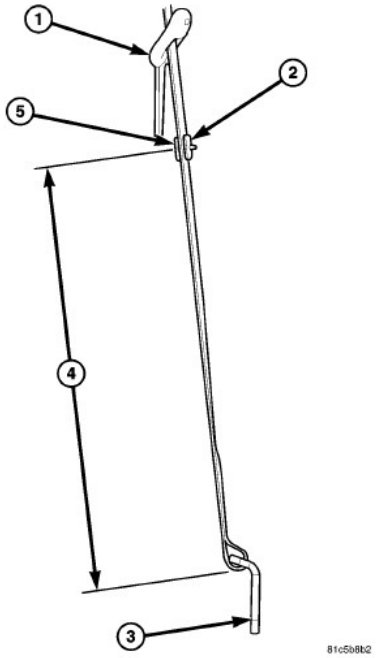
STANDARD PROCEDURE - WEB STOP BUTTON REPLACEMENT

WARNING: **To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.**

The webbing of the second row center seat belt tip half for this vehicle is equipped with a molded plastic web stop button, which holds the latch plate of the seat belt tip half in a readily accessible stored position and prevents it from falling to the lower belt anchor while the belt is not in use. If this button becomes damaged or separated from the belt webbing, it may be successfully replaced using the following procedure without the need for removing or replacing the entire seat belt assembly.

The web stop button replacement kit includes two molded plastic replacement button halves: a male button half with a pointed spike in its center, and a female button half with a hole in its center. The button halves are not available separately. In addition to the button replacement kit, a pair of wheel weight pliers (such as KD Tools® #3358, Snap-on® #WWPR13A or equivalent) and a gel-type super adhesive glue (such as Mopar® Bond-All Gel #04467709 or equivalent) are required.



NOTE: Avoid using heavy-duty, truck-style wheel weight pliers as the jaws may not close far enough to successfully complete web stop button replacement.

1. Carefully inspect the seat belt webbing to identify the hole or a witness mark where the original web stop button halves (2 and 5) were installed. If no distinct evidence of the prior button location is found, go to Step 2. If the original button location is clearly evident, go to Step 3.
2. Find the appropriate dimension in the Web Stop Button Location table. Measure and mark that distance (4) in the center of the belt webbing from the point where the webbing is secured to the seat belt lower anchor plate (3).

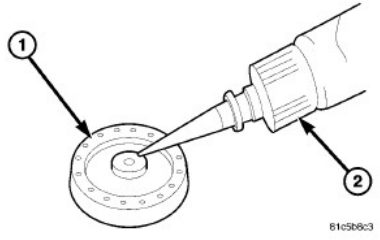
WEB STOP BUTTON LOCATION

SEATING POSITION	DIMENSION
SECOND ROW CENTER	260 plus or minus 5 millimeters (10.24 plus or minus 0.20 inches)

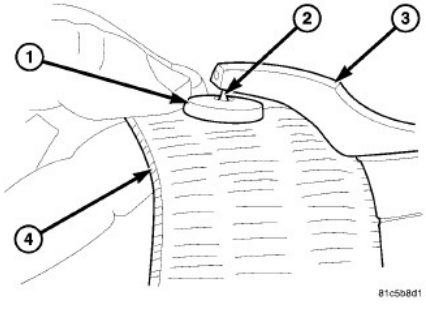
CAUTION: **Be certain that the seat belt latch plate (1) is located and secured above the web stop button location mark before installing the replacement button.**

3. Working from the side of the seat belt webbing that faces the interior of the vehicle, pierce the webbing with the spike in the center of the male button half. The male button head should face the interior of the vehicle.
4. Apply a small dot of gel-type super adhesive glue (2) around the center hole on the back side of the female button half (1).

5. Press the female button half over the spike of the male button half that protrudes through the side of the belt webbing that faces away from the interior of the vehicle.

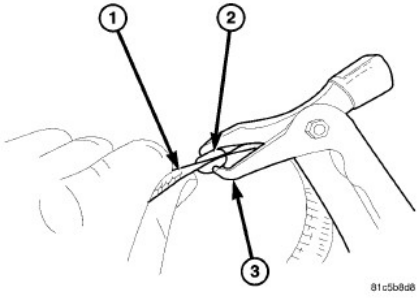


6. Use the flat anvil-like jaw (3) of the wheel weight pliers to flatten the sharp spike (2) of the male button half that protrudes through the female button half (1) on the back side of the belt webbing (4).



7. Carefully use the curved jaw (3) of the wheel weight pliers to compress and form the flattened spike of the male button half (2) on the back side of the seat belt webbing (1) until it is concave and entirely below the outer convex surface of the female button half.

8. Check to be certain that the web stop button is secure.



2014 Dodge JC - DODGE JOURNEY

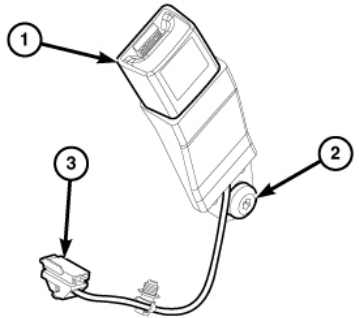
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The driver and passenger side front seat belt switches for this vehicle are actually Hall Effect-type sensors. These sensors consist of a fixed-position, Hall Effect Integrated Circuit (IC) chip and a small permanent magnet that is integral to each front seat belt buckle (1). The front seat belt buckles are located on a molded plastic scabbard and secured by a screw (2) to the inboard side of each front seat cushion frame so that the buckles travel with the seat.

The front seat belt switches are connected to the vehicle electrical system through a two-lead pigtail wire and connector (3) on the front seat belt buckle-half, which is connected to a wire harness connector and take out of the seat wire harness. A one kilohm diagnostic resistor is connected in parallel with the IC where the two pigtail wire leads connect to the IC pins.

The seat belt switches cannot be adjusted or repaired and, if ineffective or damaged, the entire front seat belt buckle-half unit must be replaced.



3085925

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The front seat belt switches are designed to control a hard wired sense input to the Occupant Restraint Controller (ORC). A spring-loaded slide with a small window-like opening is integral to the buckle latch mechanism. When a seat belt tip-half is inserted and latched into the seat belt buckle, the slide is pushed downward and the window of the slide exposes the Hall Effect Integrated Circuit (IC) chip within the buckle. The field of the permanent magnet induces a current within the chip. The chip provides this induced current as an output to the ORC. When the seat belt is unbuckled, the spring-loaded slide moves upward and shields the IC from the field of the permanent magnet, causing the output current from the seat belt switch to be reduced.

The seat belt switches receive a supply of current from the ORC, and the ORC senses the status of the front seat belt switches through its connection to the seat wire harness. The ORC provides electronic **seat belt switch status** messages to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) over the Controller Area Network (CAN) data bus. The IC uses these messages as an additional logic input for control of the seat belt indicator. The ORC monitors the condition of the seat belt switch circuits and will store a Diagnostic Trouble Code (DTC) for any fault that is detected.

The hard wired circuits between the seat belt switches and the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the switches or the electronic controls and communication between other modules and devices that provide some features of the seat belt reminder system. The most reliable, efficient and accurate means to diagnose the seat belt switches or the electronic controls and communication related to seat belt switch operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

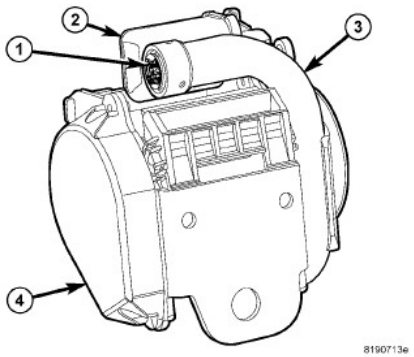
DESCRIPTION

In vehicles manufactured for domestic markets, the passenger side front seat belt incorporates dual tensioners: one integral to the retractor, and one integral to the buckle. In vehicles manufactured for export markets, the passenger side front seat belt uses a single retractor tensioner. The driver side retractor for all markets incorporates a single retractor tensioner.

RETRACTOR TENSIONER

Seat belt retractor tensioners supplement the dual front airbag system for all versions of this vehicle. These tensioners are integral to the front seat belt and retractor units (4), which are secured to the inner B-pillar on the right and left sides of the vehicle. The retractor is concealed beneath the molded plastic inner B-pillar trim. The seat belt tensioner consists primarily of a sprocket/pinion, a steel tube (3), a cast metal housing, numerous steel balls, a stamped metal ball trap (2), a torsion bar and a small pyrotechnically activated gas generator with a connector receptacle (1).

All of these components are located on one side of the retractor spool on the outside of the retractor housing except for the torsion bar, which serves as the spindle upon which the retractor spool rides. The seat belt tensioners are controlled by the Occupant Restraint Controller (ORC) and are connected to the vehicle electrical system through a dedicated take outs of the body wire harness by keyed and latching yellow molded plastic connector insulator to ensure a secure connection.



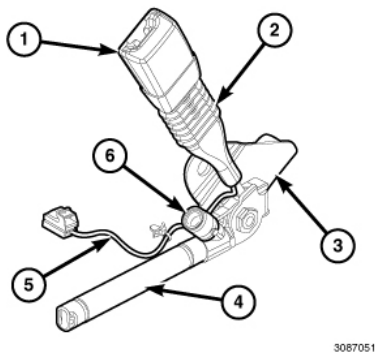
The retractor tensioners cannot be repaired and, if ineffective or damaged, the entire front seat belt and retractor unit must be replaced. If the front airbags have been deployed, the seat belt tensioners have also been deployed. The seat belt tensioners are not intended for reuse and must be replaced following any front airbag deployment. A growling or grinding sound while attempting to operate the seat belt retractor is a sure indication that the seat belt tensioner has been deployed and requires replacement. (Refer to 10 - Restraints/RETRACTOR, Seat Belt - Removal) .

BUCKLE TENSIONER

A passenger side seat belt buckle tensioner supplements the dual front airbags for domestic market versions of this vehicle. This tensioner is integral to the right front seat belt buckle unit, which is secured by a large screw to the outside of the inboard seat cushion frame of the front seat. The buckle tensioner consists primarily of a buckle (1), a molded plastic scabbard (2), a cable and piston, a cable guide and bracket (3), a metal cylinder tube (4) and a small pyrotechnically activated gas generator (6).

The buckle tensioner is controlled by the Occupant Restraint Controller (ORC) and is connected to the vehicle electrical system through a dedicated take out of the seat wire harness by a keyed and latching yellow molded plastic connector insulator to ensure a secure connection. The buckle tensioner has a single pigtail harness (5) for the integral seat belt switch.

The buckle tensioner cannot be repaired and, if ineffective or damaged, the entire front seat belt buckle unit must be replaced. If the front airbags have been deployed, the buckle tensioners have also been deployed. The buckle tensioners are not intended for reuse and must be replaced following any front airbag deployment. (Refer to 10 - Restraints/BUCKLE, Seat Belt - Removal) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The seat belt tensioners are deployed in conjunction with the dual front airbags by a signal generated by the Occupant Restraint Controller (ORC) through the driver or passenger seat belt tensioner line 1 and line 2 (or squib) circuits. When the ORC sends the proper electrical signal to the tensioners, the electrical energy generates enough heat to initiate a small pyrotechnic gas generator.

On the retractor tensioner, the gas generator is installed in one end of a steel tube that contains numerous steel balls. As the gas expands, it pushes the steel balls through the tube into a cast metal housing, where a ball guide directs the balls into engagement with the teeth of a sprocket that is geared to one end of the retractor spool. As the balls drive past the sprocket, the sprocket turns and drives the seat belt retractor spool causing the slack to be removed from the front seat belts. The ball trap captures the balls as they leave the sprocket and are expelled from the housing.

On the buckle tensioner, the gas generator is installed in one end of the tubular metal piston housing, which contains a piston secured to one end of a cable. The cable is routed around an integral guide to the buckle, which is secured to the opposite end of the cable. As the gas expands, it pushes the piston and the cable through the tube and pulls the buckle downward, causing the slack to be removed from the passenger side front seat belt.

Removing excess slack from the front seat belts not only keeps the occupants properly positioned for an airbag deployment following a frontal impact of the vehicle, but also helps to reduce injuries that the occupants of the front seats might experience in these situations as a result of harmful contact with the steering wheel, steering column, instrument panel or windshield. The seat belt retractor also has a torsion bar mechanism that is designed to deform in order to control the loading being applied to the occupants by the seat belts during a frontal impact, further reducing the potential for occupant injuries.

The ORC monitors the condition of the seat belt tensioners through circuit resistance, and will illuminate the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and store a Diagnostic Trouble Code (DTC) for any fault that is detected. Proper diagnosis of the seat belt tensioner gas generator and squib circuits requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate diagnostic information.

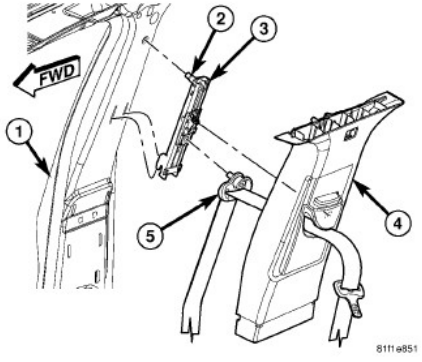
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.



1. Position the seat belt turning loop height adjuster (3) to the upper inner B-pillar (1).
2. Engage the tabs at the bottom of the height adjuster into the slots in the B-pillar.
3. Install and tighten the screw (2) that secures the height adjuster to the B-pillar. Tighten the screw to 58 N·m (43 ft. lbs.).
4. Position the seat belt turning loop onto the height adjuster on the upper B-pillar. Be certain the seat belt webbing is not twisted between the turning loop and the web guide or between the turning loop and the lower anchor.
5. Install and tighten the screw (2) that secures the turning loop to the height adjuster. Tighten the screw to 37 N·m (27 ft. lbs.).
6. Reinstall the upper trim (4) onto the inside of the B-pillar. (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Installation) .

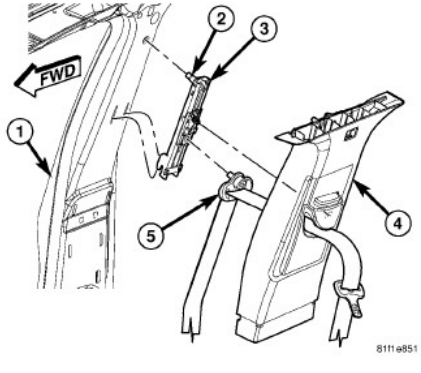
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.



1. Adjust the front seat to its most forward position for easiest access to the B-pillar trim.
2. Remove the upper trim (4) from the B-pillar (1). (Refer to 23 - Body/Interior/PANEL, B-Pillar Trim - Removal) .
3. Remove the screw that secures the seat belt turning loop (5) to the height adjuster (3) on the upper B-pillar.
4. Remove the seat belt turning loop from the height adjuster.
5. Remove the screw (2) that secures the top of the height adjuster to the B-pillar.
6. Disengage the tabs at the bottom of the height adjuster from the slots in the B-pillar.
7. Remove the adjuster from the B-pillar.

2014 Dodge JC - DODGE JOURNEY

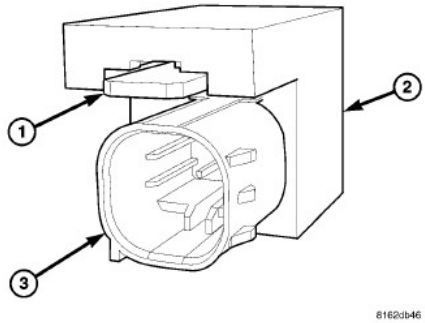
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The Seat Track Position Sensor (STPS) (2) is a Hall Effect-type sensor used on some vehicles. This sensor consists of a Hall Effect Integrated Circuit (IC) chip encased in potting material within a cavity of the molded plastic sensor housing.

The STPS housing has a mounting slot containing an integral latch feature (1) and slides and latches onto a stamped metal blade-type bracket located on the inboard side of the upper inboard seat adjuster track near the rear of the driver or passenger side front seat. A molded connector receptacle (3) integral to the STPS housing is connected to the vehicle electrical system through a connector and take out of the driver or passenger side front seat wire harness beneath the front seat cushion frame.

The STPS cannot be adjusted or repaired and, if ineffective or damaged, the entire STPS unit must be replaced.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Seat Track Position Sensor (STPS) is designed to provide a seat position data input to the Occupant Restraint Controller (ORC) indicating whether the driver or passenger side front seat is in a full forward or a not full forward position. The ORC uses this data as an additional logic input for use in determining the appropriate deployment force to be used when deploying the multistage Driver AirBag (DAB) or Passenger AirBag (PAB).

The STPS receives a nominal five volt supply from the ORC. The STPS communicates the seat position by modulating the voltage returned to the ORC on a sensor data circuit. The ORC also monitors the condition of the STPS circuits and will store a Diagnostic Trouble Code (DTC) for any fault that is detected. The ORC sends messages over the CAN data bus to control the illumination of the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC).

The hard wired circuits between the STPS and the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the STPS or the electronic controls and communication between other modules and devices that provide features of the Supplemental Restraint System (SRS). The most reliable, efficient and accurate means to diagnose the STPS or the electronic controls and communication related to STPS operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the supplemental restraint system before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor, or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the supplemental restraint system. Failure to take the proper precautions could result in accidental airbag deployment.**

1. Disconnect and isolate the negative cable from the battery. Wait two minutes for the system capacitor to discharge before further service.
2. Reach under the rear edge of the front seat cushion to access the Seat Track Position Sensor (STPS) (2) on a bracket (1) located on the inboard side near the rear of the upper inboard seat track (4).
3. Using a small screwdriver, hold the latch feature (3) depressed while sliding the connector end of the STPS off of the bracket.
4. Disconnect the seat wire harness connector (5) from the STPS connector receptacle.
5. Remove the STPS from under the front seat.

HANDLING NON-DEPLOYED SUPPLEMENTAL RESTRAINTS

At no time should any source of electricity be permitted near the inflator on the back of a non-deployed airbag or seat belt tensioner. When carrying a non-deployed airbag, the trim cover or airbag cushion side of the unit should be pointed away from the body to minimize injury in the event of an accidental deployment. If the airbag unit is placed on a bench or any other surface, the trim cover or airbag cushion side of the unit should be face up to minimize movement in the event of an accidental deployment.

When handling a non-deployed seat belt tensioner, take proper care to keep fingers out from under the retractor cover and away from the seat belt webbing where it exits from the retractor cover. In addition, the Supplemental Restraint System (SRS) should be disarmed whenever any steering wheel, steering column, seat belt tensioner, airbag, impact sensor or instrument panel components require diagnosis or service. Failure to observe this warning could result in accidental airbag deployment and possible personal injury.

All damaged, ineffective or non-deployed airbags and seat belt tensioners which are replaced on vehicles are to be handled and disposed of properly. If an airbag or seat belt tensioner unit is ineffective or damaged and non-deployed, refer to the Hazardous Substance Control System for information regarding the potentially hazardous properties of the subject component and the proper safe handling procedures. Then dispose of all non-deployed and deployed airbags and seat belt tensioners in a manner consistent with state, provincial, local and federal regulations.

SERVICE AFTER A PEDESTRIAN PROTECTION DEPLOYMENT

COMPONENT REPLACEMENT AND INSPECTION REQUIREMENTS

There are two types of Electronic Pedestrian Protection (EPP) system deployments that may occur: pedestrian and non-pedestrian. Following either type of deployment, the Electronic Vehicle Information Center (EVIC) within the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) will display a **SERVICE ACTIVE HOOD** message and the airbag indicator will be illuminated. To ensure continued system integrity, certain components must be replaced or inspected following a deployment based upon the deployment type.

NON-PEDESTRIAN DEPLOYMENT

The following components **must** be replaced following a non-pedestrian Electronic Pedestrian Protection (EPP) system deployment:

- Right and left EPP hood hinge actuators
- Right and left active hood hinge reset buttons
- Right and left active hood hinge shear rivets (see **NOTE 1**)

Following three EPP deployments the Electronic Pedestrian Protection Module (EPPM) will log a **DEPLOYMENT DATA RECORD FULL** Diagnostic Trouble Code (DTC). This DTC cannot be overwritten or cleared. In this instance, the EPPM **must** also be replaced with a new unit.

The following components **must** be closely inspected, then replaced if any damage is visually evident following a non-pedestrian deployment:

- EPP impact sensors
- EPP impact sensor wiring
- EPP safing sensors
- EPP safing sensor wiring
- Front bumper energy absorber foam material (inspect for compression, cracks and any other signs of deformation or deterioration)
- Front bumper support beam (reinforcement)
- Front fascia
- Front fascia brackets
- Hood hinges
- Hood latch/secondary catch unit
- Hood latch striker
- Hood panel
- Pedestrian bar (see **NOTE 2**)

NOTE:

1. In order to guarantee continued Electronic Pedestrian Protection (EPP) system integrity, the active hood hinges and hood panel MUST be replaced following three EPP deployments, regardless of how the active hood is deployed or the results of any visual inspection.

2. The pedestrian bar MUST be inspected and replaced if visually damaged following ANY frontal vehicle impact, regardless of whether the active hood is deployed or how the impact occurred.

PEDESTRIAN DEPLOYMENT

The following Electronic Pedestrian Protection (EPP) system components **must** be replaced following a pedestrian deployment:

- Right and left EPP hood hinge actuators
- Right and left active hood hinges
- Hood panel

Following three EPP system deployments the Electronic Pedestrian Protection Module (EPPM) will log a **DEPLOYMENT DATA RECORD FULL** Diagnostic Trouble Code (DTC). This DTC cannot be overwritten or cleared. In this instance, the EPPM **must** also be replaced with a new unit.

The following components **must** be closely inspected, then replaced if any damage is visually evident following a pedestrian deployment:

- EPP impact sensors
- EPP impact sensor wiring
- EPP safing sensors
- EPP safing sensor wiring
- Front bumper energy absorber foam material (inspect for compression, cracks and any other signs of deformation or deterioration)
- Front bumper support beam (reinforcement)
- Front fascia
- Front fascia brackets
- Hood latch/secondary catch unit
- Hood latch striker
- Pedestrian bar (see **NOTE 2**)

NOTE:

1. In order to guarantee continued Electronic Pedestrian Protection (EPP) system integrity, the active hood hinges and hood panel MUST be replaced following three EPP deployments, regardless of how the active hood is deployed or the results of any visual inspection.

2. The pedestrian bar MUST be inspected and replaced if visually damaged following ANY frontal vehicle impact, regardless of whether the active hood is deployed or how the impact occurred.

ACTIVE HOOD HINGE RESET

If the vehicle remains otherwise safely operable following an Electronic Pedestrian Protection (EPP) deployment, a customer reset position for the active hood hinges is provided to restore adequate forward visibility to drive the vehicle to the nearest dealer for service. Proceed as follows to engage the deployed active hood hinges in the reset position:

1. Push downward on one rear corner of the hood panel.

NOTE: The initial 15 millimeters (0.60 inch) of travel will require significant effort, up to 300 Newtons (68 pounds) of force. After the initial travel, the deployed EPP actuators will vent and the required force to push the hood downward will be reduced.

2. Continue pushing the hood downward until the active hinge reset mechanism engages. The rear edge of the hood will be raised about 5 millimeters (0.20 inch) higher than the fender when the active hood hinge is in the reset position.

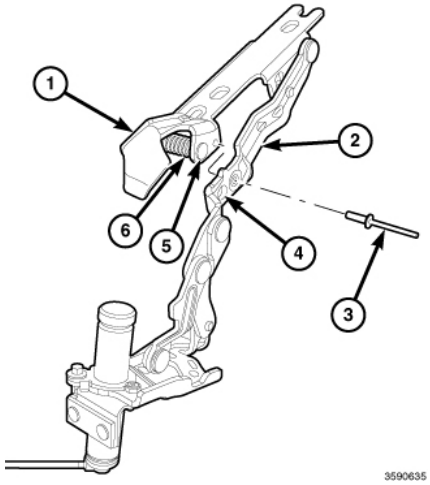
3. Repeat Steps 1 and 2 on the opposite rear corner of the hood panel.

ACTIVE HOOD HINGE SHEAR RIVET REPLACEMENT

In order to guarantee continued Electronic Pedestrian Protection (EPP) system integrity the active hood hinge shear rivet and the reset button in each active hood hinge **must** be replaced following any non-pedestrian deployment using **only** replacement parts specified in the Chrysler Mopar® Parts Catalog and the following procedure.

WARNING: **Following a pedestrian deployment or three non-pedestrian deployments, both active hood hinges and the hood panel MUST be replaced with new units. . Failure to comply with these instructions could result in an improper or incomplete active hood deployment**

and increased or fatal pedestrian injuries.



1. Open and prop the hood up in the open position.
2. Remove the remnants of the used shear rivets (3) from both the right and left hinge mid-straps (2) using one of the following methods:
    a. Firmly grasp the end of the shear rivet with side cutters and pull it out of the mid-strap using care not to damage or enlarge the hole from which the rivet is removed.
    b. Use a punch no larger than 4.76 millimeters (0.187 inch) to drive the remnant of the used shear rivet out of the mid-strap using care not to damage or enlarge the hole from which the rivet is removed.
3. Disengage the reset cap (6) from the mid-strap by pushing inward on the cap through the reset hole (4) and pulling lightly upward on the rear corner of the hood panel.
4. Place the concave surface of the new reset button (5) against the convex surface of the reset cap protruding from the hinge hood bracket (1).
5. While holding the reset button against the reset cap, push the rear corner of the hood panel downward far enough to capture the button between the hood bracket and the mid-strap, preventing the spring-actuated reset cap from engaging in the reset hole.
6. Move the rear corner of the hood panel up or down as needed to align the shear rivet holes in the hinge hood bracket and the mid-strap.
7. Insert the new shear rivet through the outboard side of the mid-strap, then through the hood bracket.

WARNING: **Be certain to hold the blind rivet installation tool so that the head of the shear rivet remains flush against the hinge mid-strap during rivet expansion. Do not twist the installation tool or rock it from side-to-side to break the rivet mandrel. The rivet mandrel must be broken in tension to ensure the mandrel does not extend through the shear joint, which will prevent the hood from lifting as designed during a subsequent deployment. Failure to comply with these instructions could result in improper or incomplete active hood deployment and increased or fatal pedestrian injuries.**

8. Expand the shear rivet using a blind rivet installation tool and nose piece with adequate capacity to break the rivet mandrel in tension.
9. Following shear rivet installation, verify that the rivet mandrel is at least 5.5 millimeters (0.22 inch) below the head of the rivet by measuring the depth that a pin or drill bit less that 2.5 millimeters (0.10 inch) in diameter can be inserted into the mandrel hole in the head of the rivet.

Fuel Delivery: | **Fuel:**

SERVICE AFTER A SUPPLEMENTAL RESTRAINT SYSTEM DEPLOYMENT

Any vehicle which is to be returned to use following a Supplemental Restraint System (SRS) component deployment must have the deployed restraints replaced. In addition, the following guidelines MUST be observed.

- **Following ANY major vehicle impact damage in the vicinity of an impact sensor or the ORC** - It is critical that the mounting surfaces and mounting brackets for the Occupant Restraint Controller (ORC), front impact sensors and side impact sensors located within the proximity of the impact damage be closely inspected and restored to their original conditions. Because the ORC and each impact sensor are used by the SRS to monitor or confirm the direction and severity of a vehicle impact, improper orientation or insecure fastening of these components may cause airbags not to deploy when required, or to deploy when not required.
- **If an active head restraint is deployed** - Deployed Active Head Restraint (AHR) units that are undamaged are designed with the intention of reuse. However, the deployed AHR units must be properly reset following deployment. (Refer to 10 - Restraints/RESTRAINT, Active Head - Standard Procedure) .
- **If the driver airbag is deployed** - If the Driver AirBag (DAB) has been deployed, the clockspring and the steering column must be replaced.
- **If the knee airbag is deployed** - On vehicles so equipped, if the Knee AirBag (also known as the Inflatable Knee Blocker/IKB) has been deployed, the instrument panel steering column opening cover must also be replaced.
- **If the passenger airbag is deployed** - If the Passenger AirBag (PAB) has been deployed, the instrument panel top pad must also be replaced.
- **If a seat airbag is deployed** - If a Seat AirBag (SAB) (also known as the pelvic and thoracic airbags) has been deployed, the seat back frame, the seat back foam and the seat back trim cover on the same side of the vehicle as the deployed airbag must also be replaced.
- **If a seat belt tensioner is deployed** - The seat belt tensioners are deployed in conjunction with the front airbags, but can also be deployed with a Seat AirBag (SAB) (also known as the pelvic and thoracic airbag) or side curtain airbags (also known as Side AirBag Inflatable Curtain/SABIC). The seat belt tensioners must be replaced if either front airbag has been deployed, and must be inspected if either SAB or side curtain airbag has been deployed.
- **If a side curtain airbag is deployed** - If a side curtain airbag (also known as Side AirBag Inflatable Curtain/SABIC) has been deployed, the headliner as well as the upper A, B, C and, on vehicles with the optional seven-passenger seating, the D-pillar trim on the same side of the vehicle as the deployed airbag must also be replaced. On vehicles with an optional sunroof, the sunroof drain tubes and hoses must be closely inspected following a side curtain airbag deployment.

The components identified with the deployed SRS components in the preceding list are not intended for reuse and will be damaged or weakened as a result of an airbag deployment, which may or may not be obvious during a visual inspection. All other vehicle components should be closely inspected following any SRS component deployment, but are to be replaced only as required by the extent of the visible damage incurred.

SQUIB CIRCUIT DAMAGE

In addition to the preceding guidelines, be aware that the heat created by the initiator during an airbag or tensioner deployment will cause collateral damage to the connected wiring (squib circuits) and connector insulators. There are two methods by which an airbag or seat belt tensioner may be connected to the vehicle electrical system. The first method involves a short pigtail harness and connector insulator that are integral to the airbag or tensioner unit and are replaced as a unit with the service replacement airbag or seat belt tensioner. This connection method typically requires no additional wiring repair following a deployment.

However, the second connection method involves a wire harness takeout and connector insulator that are connected directly to the airbag or tensioner initiator or squib. These direct-connect type take outs and connector insulators **MUST** be repaired following an airbag or seat belt tensioner deployment using the approved Supplemental Restraint System Wiring Repairs procedure. (Refer to 10 - Restraints - Standard Procedure) .

AIRBAG SQUIB STATUS

Multistage airbags with multiple initiators (squibs) must be checked to determine that all squibs were used during the deployment event. The Driver AirBag (DAB) and Passenger AirBag (PAB) in this vehicle are deployed by electrical signals generated by the Occupant Restraint Controller (ORC) through the driver or passenger squib 1 and squib 2 circuits to the two initiators in the airbag inflators. Typically, both initiators are used and all potentially hazardous chemicals are burned during an airbag deployment event. However, it is possible for only one initiator to be used; therefore, it is always necessary to confirm that both initiators have been used in order to avoid the improper handling or disposal of potentially live pyrotechnic or hazardous materials. The following procedure should be performed using a diagnostic scan tool to verify the status of both airbag squibs before either deployed airbag is removed from the vehicle for disposal.

CAUTION: **Deployed front airbags having two initiators (squibs) in the airbag inflator may or may not have live pyrotechnic material within the inflator. Do not dispose of these airbags unless you are certain of complete deployment. Refer to the Hazardous Substance Control System for information regarding the potentially hazardous properties of the subject component and the proper safe handling procedures. Then dispose of all non-deployed and deployed airbags and seat belt tensioners in a manner consistent with state, provincial, local and federal regulations.**

1. Be certain that the diagnostic scan tool contains the latest version of the proper diagnostic software. Connect the scan tool to the 16-way Data Link Connector (DLC). The DLC is located on the driver side lower edge of the instrument panel, outboard of the steering column.
2. Transition the status of the ignition switch to On.
3. Using the scan tool, read and record the active (current) Diagnostic Trouble Code (DTC) data.

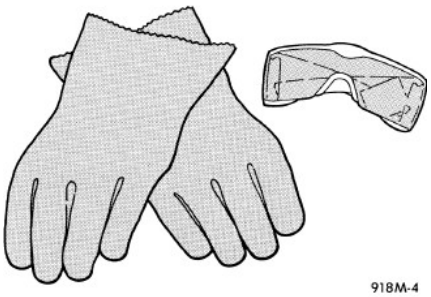
Using the active DTC information, refer to the **Airbag Squib Status** table to determine the status of both DAB squibs and both PAB squibs.

AIRBAG SQUIB STATUS		
IF THE ACTIVE DTC IS:	CONDITIONS	SQUIB STATUS
Driver or Passenger Squib 1 open Driver or Passenger Squib 2 open	**AND** the stored DTC minutes for both Driver or Passenger squibs are within 15 minutes of each other	Both Squib 1 and 2 were used.
Driver or Passenger Squib 1 open Driver or Passenger Squib 2 open	**AND** the stored DTC minutes for Driver or Passenger Squib 2 open is GREATER than the stored DTC minutes for Driver or Passenger Squib 1 by 15 minutes or more	Squib 1 was used; Squib 2 is live.
Driver or Passenger Squib 1 open Driver or Passenger Squib 2 open	**AND** the stored DTC minutes for Driver or Passenger Squib 1 open is GREATER than the stored DTC minutes for Driver or Passenger Squib 2 by 15 minutes or more	Squib 1 is live; Squib 2 was used.
Driver or Passenger Squib 1 open	**AND** Driver or Passenger Squib 2 open is NOT an active code	Squib 1 was used; Squib 2 is live.
Driver or Passenger Squib 2 open	**AND** Driver or Passenger Squib 1 open is NOT an active code	Squib 1 is live; Squib 2 was used.

NOTE: If none of the Driver or Passenger Squib 1 or 2 open are active codes, the status of the airbag squibs is unknown. In this case the airbag should be handled and disposed of as if the squibs were both live.

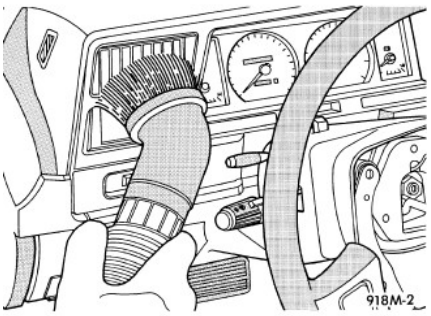
CLEANUP PROCEDURE

Following a Supplemental Restraint System (SRS) component deployment, the vehicle interior will contain a powdery residue. This residue consists primarily of harmless particulate by-products of the small pyrotechnic charge that initiates the propellant used to deploy a SRS component. However, this residue may also contain traces of sodium hydroxide powder, a chemical by-product of the propellant material that is used to generate the inert gas that inflates the airbag. Since sodium hydroxide powder can irritate the skin, eyes, nose, or throat, be certain to wear safety glasses, rubber gloves, and a long-sleeved shirt during cleanup.



WARNING: **To avoid serious or fatal injury, if you experience skin irritation during cleanup, run cool water over the affected area. Also, if you experience irritation of the nose or throat, exit the vehicle for fresh air until the irritation ceases. If irritation continues, see a physician.**

1. Begin the cleanup by using a vacuum cleaner to remove any residual powder from the vehicle interior. Clean from outside the vehicle and work your way inside, so that you avoid kneeling or sitting on a non-cleaned area.
2. Be certain to vacuum the heater and air conditioning outlets as well. Run the heater and air conditioner blower on the lowest speed setting and vacuum any powder expelled from the outlets.



CAUTION: **Deployed front airbags having two initiators (squibs) in the airbag inflator may or may not have live pyrotechnic material**

within the inflator. Do not dispose of these airbags unless you are certain of complete deployment. Refer to the AIRBAG SQUIB STATUS heading within this information. All damaged, ineffective, or non-deployed Supplemental Restraint System (SRS) components which are replaced on vehicles are to be handled and disposed of properly. If an airbag or seat belt tensioner unit is ineffective or damaged and non-deployed, refer to the Hazardous Substance Control System for information regarding the potentially hazardous properties of the subject component and the proper safe handling procedures. Then dispose of all non-deployed and deployed airbags and seat belt tensioners in a manner consistent with state, provincial, local and federal regulations.

3. Next, remove the deployed SRS components from the vehicle. Refer to the appropriate service removal procedures.

4. You may need to vacuum the interior of the vehicle a second time to recover all of the powder.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

SUPPLEMENTAL RESTRAINT STORAGE

Airbags and seat belt tensioners must be stored in their original, special container until they are used for service. Also, they must be stored in a clean, dry environment away from sources of extreme heat, sparks and high electrical energy. Always place or store any airbag on a surface with its trim cover or airbag cushion side facing up, to minimize movement in case of an accidental deployment.

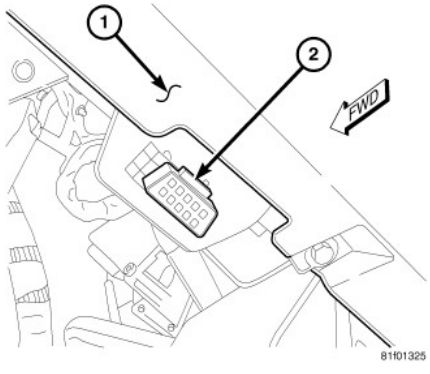
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

SUPPLEMENTAL RESTRAINT SYSTEM VERIFICATION TEST

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: The following procedure should be performed using a diagnostic scan tool to verify proper Supplemental Restraint System (SRS) operation following the service or replacement of any SRS component. Refer to the appropriate diagnostic procedures.



1. During the following test, the negative cable remains disconnected and isolated from the battery, as it was during the Supplemental Restraint System (SRS) component removal and installation procedures.
2. Be certain that the diagnostic scan tool contains the latest version of the proper diagnostic software. Connect the scan tool to the 16-way Data Link Connector (DLC) (2). The DLC is located on the driver side lower edge of the instrument panel within a rectangular cutout in the lower instrument panel reinforcement, just forward of the instrument panel steering column opening cover (1).
3. Transition the status of the ignition switch to On and exit the vehicle with the scan tool.
4. Check to be certain that nobody is in the vehicle, then reconnect the negative cable to the battery.
5. Using the scan tool, read and record the active (current) Diagnostic Trouble Code (DTC) data.
6. Next, use the scan tool to read and record any stored (historical) DTC data.
7. If any DTC is found in Step 5 or Step 6, refer to the appropriate diagnostic information.
8. Use the scan tool to erase the stored DTC data. If any problems remain, the stored DTC data will not erase. Refer to the appropriate diagnostic information to diagnose any stored DTC that will not erase. If the stored DTC information is successfully erased, go to Step 9.
9. Transition the status of the ignition switch to Off for about 15 seconds, and then back to On. Observe the airbag indicator in the instrument cluster. It should light from four to six seconds, and then go out. This indicates that the SRS is functioning normally and that the repairs are complete. If the airbag indicator fails to light, or lights and stays On, there is still an active SRS fault or malfunction. Refer to the appropriate diagnostic information to diagnose the problem.

SUPPLEMENTAL RESTRAINT SYSTEM WIRING REPAIRS

Special Tools: Click to display a list of tools used in this procedure

It is important when repairing any Supplemental Restraint System (SRS) electrical circuits to use the recommended splicing kit and procedure. For applicable and available MOPAR wiring repair kits, please visit the MOPAR Connector Web Site at the following address on the internet: (http://dto.vftis.com/mopar/disclaimer.asp).

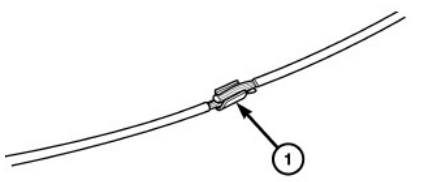
This recommended procedure involves crimping the wires together with a splice band, soldering the crimped connection and, finally, sealing and protecting the repair. The crimp and solder ensure a strong mechanical bond that will always pass a pull test while also maintaining the conductivity and current carrying capacity of the circuit. The adhesive sealant and heat shrink tubing ensures the splice repair will perform as well or better than the original wire and be safe from potential corrosion or short circuits.

There is no limit to the number of splice repairs that can be made in one harness using this procedure. However, as has been past practice, multiple adjacent splices should be offset from each other. This wiring splice repair procedure is approved for harness side repairs only. Repairs and splices to pigtail wires on SRS components such as airbag units, seat belt tensioner units or clocksprings are not approved or recommended.

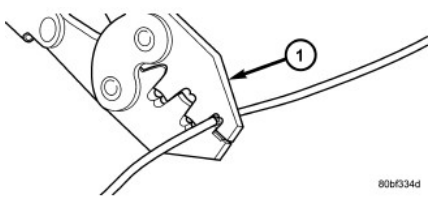
REPAIR PROCEDURE

CAUTION: **If additional wire is needed when making a splice repair to any wire, it is important that the same or next larger size wire gauge be used. Refer to the appropriate wiring diagram for the original wire gauge size.**

1. Remove 13 millimeters (0.50 inch) of insulation from each wire that needs to be spliced.
2. Place a piece of adhesive sealant-lined heat shrink tubing (Part Number 04778570 or equivalent) over the wire on one side of the splice. Be certain the length of tubing will be sufficient to cover and seal the entire repair area.
3. Place the strands of the wires being spliced so that they are overlapping each other within the splice band (1).

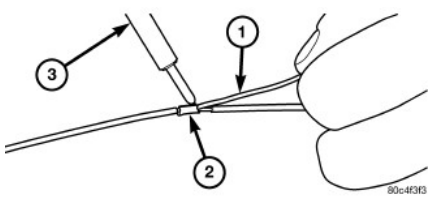


4. Using a crimping tool (1) (MOPAR Part Number 05019912AA, Miller Special Tool Number 10042 or equivalent) crimp the splice band and wires together securely.



CAUTION: **Never use acid core solder for electrical wiring repairs.**

5. Using rosin core type solder (1) only and a suitable soldering iron (3), solder the wire and splice band connection (2) together.



6. Center the heat shrink tubing (2) over the splice joint repair and heat using a suitable heat gun. Heat the joint until the tubing is tightly sealed and sealant (1) begins to ooze out of both ends of the tubing.

Fuel Delivery: | **Fuel:**

WARNING

WARNING:

To avoid serious or fatal injury on vehicles equipped with the Supplemental Restraint System (SRS), never attempt to repair the electrically conductive circuits or wiring components related to the SRS for which there is no MOPAR wiring repair kit. It is important to use ONLY the recommended splicing kit and procedure. For applicable and available MOPAR wiring repair kits, please visit the MOPAR® Connector Web Site at the following address on the internet: (http://dto.vftis.com/mopar/disclaimer.asp). Inappropriate repairs can compromise the conductivity and current carrying capacity of those critical electrical circuits, which may cause SRS components not to deploy when required, or to deploy when not required. Only minor cuts or abrasions of wire and terminal insulation where the conductive material has not been damaged, or connector insulators where the integrity of the latching and locking mechanisms have not been compromised may be repaired using appropriate methods.

WARNING:

To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler Mopar® Parts Catalog. Failure to follow these instructions may result in possible serious or fatal injury.

WARNING:

To avoid serious or fatal injury on vehicles equipped with side curtain or seat (pelvic and thorax) airbags, disable the Supplemental Restraint System (SRS) before attempting any Occupant Restraint Controller (ORC) diagnosis or service. The ORC contains a rollover sensor, which enables the system to deploy the side curtains or seat airbags in the event of a vehicle rollover event. If an ORC is accidentally rolled during service while still connected to battery power, the side curtain and seat airbags will deploy. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

WARNING:

To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

WARNING:

To avoid potential physical injury or damage to sensitive electronic circuits and systems, always disconnect and isolate the battery negative (ground) cable and the positive cable, then ground the positive cable to discharge the Occupant Restraint Controller (ORC) capacitor before performing any welding operations on the vehicle. Failure to take the proper precautions could result in accidental airbag deployment, possible damage to the Supplemental Restraint System (SRS) circuits and components, and possible damage to other electronic circuits and components. Whenever a welding process is being performed within 12 inches (30 centimeters) of an electronic module or wiring harness, then that module or harness should be relocated out of the way, or disconnected. Always protect against component or vehicle damage from weld spatter by using weld blankets and screens.

WARNING:

To avoid serious or fatal injury, do not attempt to dismantle an airbag unit or tamper with its inflator. Do not puncture, incinerate or bring into contact with electricity. Do not store at temperatures exceeding 93° C (200° F). An airbag inflator unit may contain sodium azide and potassium nitrate. These materials are poisonous and extremely flammable. Contact with acid, water, or heavy metals may produce harmful and irritating gases (sodium hydroxide is formed in the presence of moisture) or combustible compounds. An airbag inflator unit may also contain a gas canister pressurized to over 17.24 kPa (2500 psi). Failure to follow these instructions may result in possible serious or fatal injury.

WARNING:

To avoid serious or fatal injury when handling a seat belt tensioner retractor or buckle, proper care should be exercised to keep fingers out from under the retractor or buckle cover and away from the seat belt webbing or cable where it exits from the retractor or buckle cover.

WARNING:

To avoid serious or fatal injury, replace all Supplemental Restraint System (SRS) components only with parts specified in the Chrysler Mopar® Parts Catalog. Substitute parts may appear interchangeable, but internal differences may result in inferior occupant protection.

WARNING:

To avoid serious or fatal injury, the fasteners, screws, and bolts originally used for the Supplemental Restraint System (SRS) components must never be replaced with any substitutes. These fasteners have special coatings and are specifically designed for the SRS. Anytime a new fastener is needed, replace it with the correct fasteners provided in the service package or specified in the

Chrysler Mopar® Parts Catalog.

WARNING:

To avoid serious or fatal injury when a steering column has an airbag unit attached, never place the column on the floor or any other surface with the steering wheel or airbag unit face down. Failure to follow these instructions may result in possible serious or fatal injury.

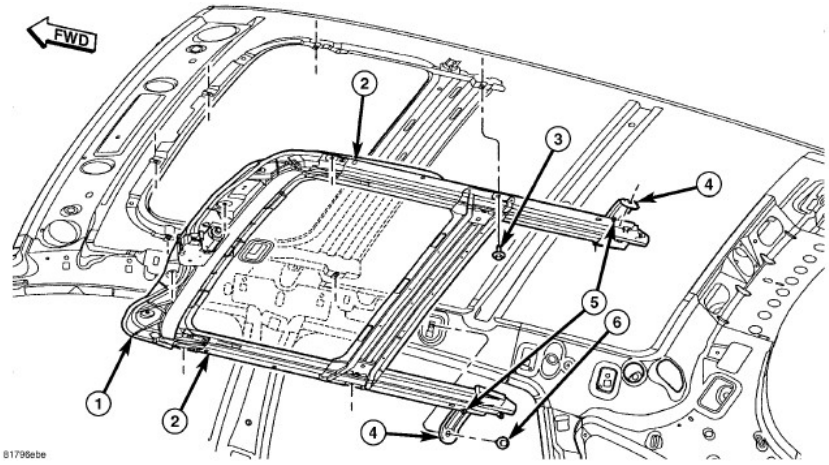
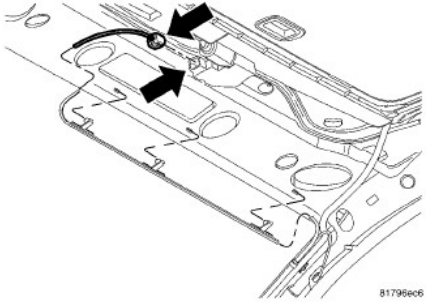
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

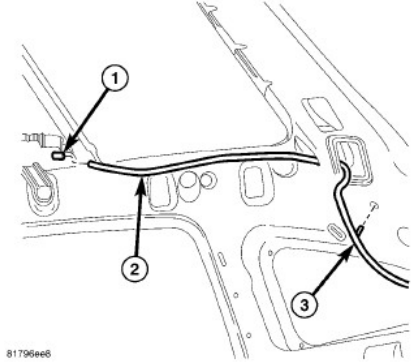


1. Install the trough guides (Refer to 23 - Body/Sunroof/TROUGH, Sunroof - Installation) .
2. Install the drive motor (Refer to 08 - Electrical/8N - Power Systems/Power Top/MOTOR, Sunroof - Installation) .
3. Install the sunshade (Refer to 23 - Body/Sunroof/SUNSHADE, Sunroof - Installation) .
4. Install the glass panel (Refer to 23 - Body/Sunroof/GLASS, Sunroof - Installation) .
5. Raise rear end of sunroof module assembly (1) and guide into position and start the six fasteners (3).
6. Visually line up the alignment guide holes (2) with the guide holes in the roof of the vehicle.
7. Tighten the six fasteners (3) to 9 N·m (80 in. lbs.).
8. Tighten the two side bracket fasteners (6) to 9 N·m (80 in. lbs.).
9. Connect the drain tubes (2) to the assembly (1).
10. Connect the electrical connector.
11. Connect the battery negative cable.
12. Test sunroof operation, adjust glass as necessary (Refer to 23 - Body/Sunroof/GLASS, Sunroof - Adjustments) .

13. Partially install the headliner and connect the sunroof wiring electrical connectors (Refer to 23 - Body/Interior /HEADLINER - Installation) .



14. Temporarily install sunroof switch and perform the sunroof motor teach procedure, (Refer to 08 - Electrical/8N - Power Systems/Power Top/MOTOR, Sunroof - Standard Procedure) .



15. Install the headliner (Refer to 23 - Body/Interior/HEADLINER - Installation) .

16. Verify correct sunroof operation.

STANDARD PROCEDURE - DRIVE MOTOR TEACH PROCEDURE

REPLACEMENT DRIVE MOTOR

1. Press and hold the sunroof switch open until the sunroof glass fully opens, automatically reverses direction, and stops at a position just forward of the full open position.
2. Release sunroof switch.
3. Within five seconds of releasing sunroof switch, press and hold the sunroof switch open again until the sunroof glass closes, goes into vent position, and then finally stops in the closed position.
4. Release sunroof switch. Sunroof will now operate normally.

ORIGINAL DRIVE MOTOR

1. Press and hold sunroof switch open until the sunroof glass opens and stops.
2. Release sunroof switch.
3. Press and hold sunroof switch open once again for at least 10 seconds. After 10 seconds of pressing the switch open, the sunroof glass will automatically move and stop at a new location.
4. Release sunroof switch.
5. Within five seconds of releasing the sunroof switch, press and hold the switch open again until the sunroof glass closes, goes into vent position, and then finally stops in the closed position.
6. Release sunroof switch. The sunroof will now operate normally.

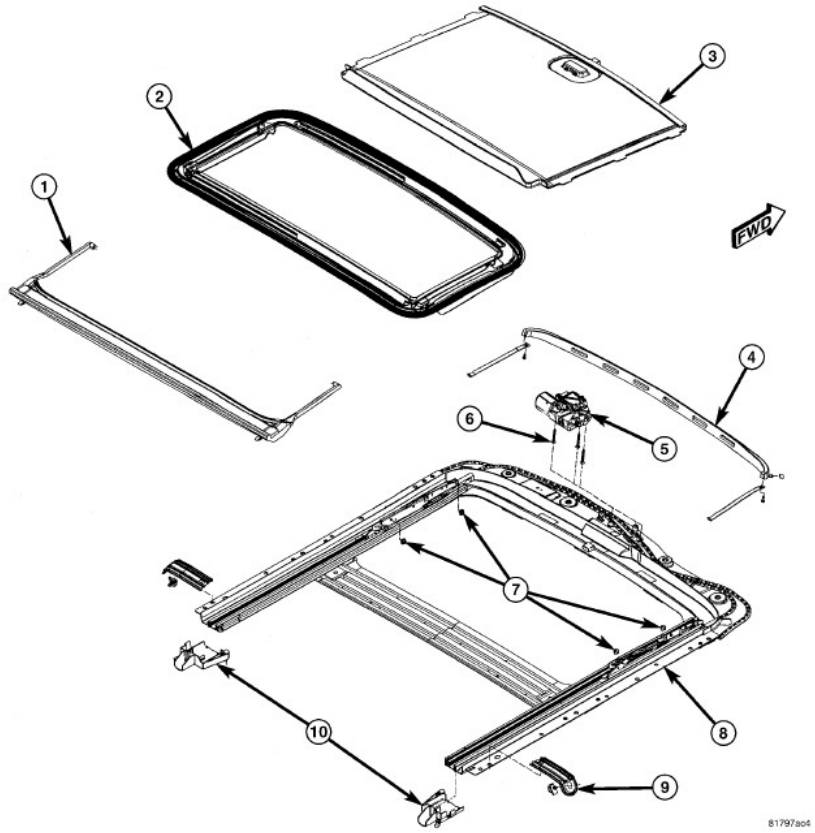
DESCRIPTION



WARNING: **Keep fingers and other body parts out of sunroof opening at all times.**

The sunroof features a power sliding glass panel and a sunshade which can be manually positioned anywhere along its travel, rearward of glass panel front edge.

The sunroof is electrically operated from two switches located on the windshield header, between the map lamp. To operate the sunroof the ignition switch must be in either the Accessory or On/Run position. One switch (vent) is a push button type and opens the sunroof to the vent position only. The other switch (open/close) is a rocker type for opening and closing the sunroof. Pressing and releasing the open button once the sunroof will express open and the wind deflector will raise. If the button is pressed a second time the sunroof will stop in that position. Pressing and holding the close button will close the sunroof. If the close button is released the sunroof will stop in that position. Also, by pressing the close button the sunroof will close automatically.

OPERATION

This vehicle has a vent, tilt and slide power sunroof system with express (one-touch) open/close feature. The sunroof system receives battery feed through the “sunroof” relay and a 25 amp mini fuse located in the Totally Integrated Power Module (TIPM). The sunroof system power is supplied when the ignition switch is in the RUN and ACCESSORY positions. The sunroof will operate normally with the key in any position while the Accessory Delay system is active.

The sunroof is electrically operated from two switches located in the overhead console in between the two reading lamps. The “VENT” switch is a push button type switch and opens the sunroof to the vent position only. The other switch “OPEN/CLOSED” is a rocker type switch for opening and closing the sunroof. Pressing and releasing the open button once, the sunroof will express open and the wind deflector will raise. If the button is pressed a second time the sunroof will stop in that position. Pressing and releasing the close button once will express close the sunroof. If the close button is pressed a second time during the express close operation the sunroof will stop in that position.

STANDARD PROCEDURE - DRIVE MOTOR TEACH PROCEDURE

REPLACEMENT DRIVE MOTOR

1. Upon first powering up the sunroof, **continuously** press the close button on the power sunroof switch. The sunroof will begin moving in the tilt up direction.
2. The glass panel will move to the hard stop (just past the full tilt position) and then reverse to the soft stop (the full tilt position).
3. Once the sunroof has reversed **immediately** (within 5 seconds of stopping travel), release the switch and **continuously** press the close button again.
4. The sunroof glass will continue to move to the fully closed position. Once fully closed the close button can be released.

ORIGINAL DRIVE MOTOR

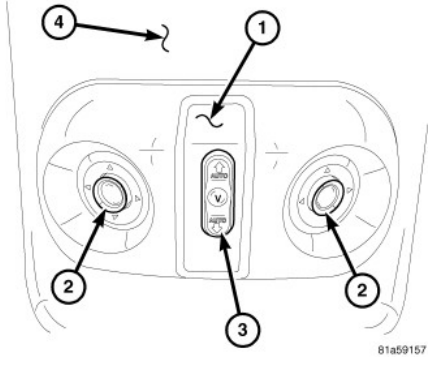
1. Cycle the sunroof to full close position and release close button on the power sunroof switch.
2. Once the sunroof is in the fully closed position, press and **continuously** hold the close button again.
3. After a ten second delay the sunroof will begin to move past the normal vent position to the hard stop position. It will then reverse to the normal full vent position (also called the soft stop).
4. Once the sunroof has reversed to the vent soft stop, **immediately** (within 5 seconds of stopping travel) release the close button and **continuously** press it again.
5. After a three second delay the sunroof glass will continue to move to the fully closed position. Once fully closed the close button can be released.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The power sunroof switch (3) is a combination push-button and rocker switch module mounted in the overhead console assembly (1). The sunroof switch is a direct contact unit that is directly wired to the sunroof motor/module assembly. The sunroof switch performs the following functions:



- Power sunroof open (back of switch pushed)
- Power sunroof express open (back of switch pushed and released)
- Power sunroof closed (front of switch pushed)
- Power sunroof express closed (front of switch pushed and released)
- Power sunroof vent (switch center button pushed)

The power sunroof switch cannot be repaired. If the individual components are damaged or inoperative the switch assembly must be replaced, (Refer to 08 - Electrical/8N - Power Systems/Power Top/SWITCH, Sunroof - Removal) .

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Insert the sunroof control switch into the overhead console assembly. Push the switch until it is securely held in place by the mounting tabs.
2. Install the overhead console.
3. Connect the battery negative cable.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The sunroof is electrically operated from two switches located in the headliner on the courtesy/reading lamp assembly. The power sunroof switch is hard wired to the sunroof motor/module assembly. The “VENT” switch is a push button type switch and opens the sunroof to the vent position only. The other switch “OPEN/CLOSED” is a rocker type switch for opening and closing the sunroof. Pressing and releasing the open button once, the sunroof will express open and the wind deflector will raise. If the button is pressed a second time the sunroof will stop in that position. Pressing and releasing the close button once will express close the sunroof. If the close button is pressed a second time during the express close operation the sunroof will stop in that position.

The switch is grounded at one terminal and receives a 5 volt signal from the sunroof motor/module on the remaining three terminals. The switch pulls down the 5 volt reference voltage from the module signaling it to perform the desired function.

For complete circuit diagrams, refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

Fuel Delivery: | **Fuel:**

OPERATION

There are 5 other component categories that make up the new ignition system.

The components are:

- Radio Frequency (RF) HUB (1)
- LF Antennas (5)
- FOB (2, 4 for Police)
- Special Door Handles (2)
- Special Liftgate Handle (1)

This new ignition system operation begins when an owner approaches their vehicle with a FOB somewhere on their person or belongings, i.e., in their gym bag. When the owner touches the handle to pull the door open, door handle electronics signal the RF HUB with a “request to open”. The RF HUB uses all of the 5 LF (low frequency) antennas to communicate with the FOB. Once located, the FOB’s response is evaluated by the RF HUB to determine if the person pulling on the door handle is in fact the owner. This process completes ‘FOB authentication’.

Once authentication is successfully completed, the RF HUB requests the Body Control Module (BCM) to unlock the affected door. Once the doors unlock, the owner is then free to continue pulling the door handle in an attempt to enter their vehicle. This process of opening the door without actively using a FOB or key is called ‘passive entry’. This vehicle when activating the passive entry switch activates the door unlock motor only. The vehicle owner must subsequently pull on the handle to open the liftgate itself.

After the vehicle’s owner is buckled, he/she pushes the KIN’s SSB (Keyless Ignition Node’s Start/Stop Button) while pushing the brake pedal as if braking while coming to a stoplight. (For manual transmission vehicles the clutch pedal is depressed instead of the brake pedal to initiate a start procedure). Before the vehicle is allowed to start, another ‘FOB authentication’ cycle must be completed. Once successfully completed, the RF HUB next sends the BCM the ignition switch position, which equates to a ‘request to start’ command. The process of starting a vehicle without the act of using a bladed key or FOB is called ‘Keyless Go’.

The passive entry works when the FOB can be located outside the vehicle using the LF antennas. Keyless go operates when the RF HUB can locate the FOB inside the vehicle. Please refer to the owner’s manual for more information on authentication zones.

After putting the vehicle into park, pushing the KIN’s SSB allows the vehicle’s engine to be shut off. In an emergency, pressing the SSB continuously for 2 seconds or repeatedly (one hit every 30- 500msec) shuts off the engine.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The remote start antenna is an external hidden antenna located between the headliner and the roof on the first support rib from the back of the vehicle. The antenna interfaces with the Radio Frequency Hub (RF Hub) through a coaxial cable. The antenna helps to amplify the signal for the Remote Keyless Entry (RKE) key fob.

DESCRIPTION

A power operated door and liftgate lock system is standard factory-installed equipment on this vehicle. The power lock system allows all of the doors and the liftgate to be locked or unlocked electrically. Locking or unlocking the vehicle using the power lock system can be accomplished by up to three different methods:

- **Power Lock System** - Operating a power lock system switch on either front door inside trim panel will lock or unlock the latches of all four doors and the liftgate.
- **Remote Keyless Entry System** - Depressing the **Lock** or **Unlock** button of the standard equipment Remote Keyless Entry (RKE) system transmitter (also known as the FOB with Integrated Key/FOBIK) can also be used to lock or unlock the latches of the doors and the liftgate. The specific locks operated and the number of FOBIK button presses required varies depending upon the Customer Programmable settings chosen by the vehicle operator.
- **Passive Entry System** - On vehicles equipped with the optional Passive Entry (PE) system, contacting the capacitive **Unlock** switch on the inside of either exterior front door Smart handle grip or depressing the tactile **Lock** button of either front door Smart handle while a valid FOBIK is identified in that same zone can be used to lock or unlock the door and liftgate latches. Also depressing the tactile **Lock/Unlock** button on the liftgate light bar/handle unit while a valid FOBIK is identified in that same zone can be used to lock or unlock the door and liftgate latches. The specific locks operated varies depending upon the Customer Programmable settings chosen by the vehicle operator.

Additional details of each of these subsystems and their components can be found in the subheadings and paragraphs that follow.

POWER LOCK SYSTEM

The power lock system includes the following major components, which are described in further detail elsewhere in this service information:

- **Body Control Module** - The Body Control Module (BCM) (also known as the Common Body Controller/CBC) is located beneath the instrument panel on the passenger side of the vehicle. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Body Control - Description) .
- **Door Modules** - The Driver Door Module (DDM) and Passenger Door Module (PDM) are located on their respective driver and passenger front door hardware module carriers and are concealed behind the front door inside trim panels. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Door - Description) .
- **Electronic Vehicle Information Center** - The Electronic Vehicle Information Center (EVIC) includes the EVIC switches and the U-Connect Touch™ screen module in the Integrated Center Stack (ICS) located in the center stack area of the instrument panel. (Refer to 08 - Electrical/8M - Message Systems/Message Center/CENTER, Electronic Vehicle Information - Description) .
- **Power Lock Motors** - A reversible electric power lock motor is integral to the latch of each front and rear door and the liftgate.
- **Power Lock Switches** - A power lock switch is integral to the switch module located on the forward end of the arm rest of each front door inside trim panel.

These components and their controls are combined to provide the following power lock system central locking and unlocking features:

- **Automatic Door Locking** - Automatic door locking (also known as rolling door locks) automatically locks any unlocked door when the vehicle speed exceeds about 25.7 kilometers per hour (15 miles per hour). This is a Customer Programmable feature except in vehicles manufactured for certain export markets. For vehicles manufactured for sale in markets where a signed authorization is required for enabling this feature, it can only be enabled and disabled by the dealer.
- **Automatic Door Unlocking** - Automatic door unlocking (also known as automatic unlock doors on exit) automatically unlocks the doors after they were automatically locked when the vehicle speed exceeded about 25.7 kilometers per hour (15 miles per hour), the vehicle speed has returned to zero, the transmission shift lever is in the **Neutral** or **Park** positions and the driver side front door is opened. This is a Customer Programmable feature except in vehicles manufactured for certain export markets. For vehicles manufactured for sale in markets where a signed authorization is required for enabling this feature, it can only be enabled and disabled by the dealer.
- **Customer Programmable Features** - The vehicle operator interfaces with the BCM, which is the power lock system controller, using the EVIC. EVIC switches allow the vehicle operator to set or change the power lock system Customer Programmable Features through the U-Connect Touch™ screen module EVIC display, except for some features in vehicles manufactured for certain export markets where these settings can only be changed by the dealer.
- **Door Lock Inhibit** - Prevents locking the doors using a power door lock switch or the **Lock** button of the Remote Keyless Entry (RKE) system transmitter (also known as the FOB with Integrated Key/FOBIK) if the key is in the ignition and the driver side front door is open.
- **Enhanced Accident Response System** - In the event of a vehicle impact that causes airbag deployment but leaves vehicle electrical power intact, the Enhanced Accident Response System (EARS) automatically turns OFF the supply of fuel to the engine, turns ON the interior courtesy lamps, turns ON the hazard warning flashers and unlocks the doors after the vehicle speed has returned to zero. This helps emergency responders in their efforts to render the appropriate assistance. The courtesy lamps and hazard flashers remain ON as long as the battery has power or until the key is removed from the ignition.
- **Illuminated Entry** - Automatic illumination of the interior courtesy lamps when the vehicle is unlocked using the power lock system.

Hard wired circuitry connects the power lock system components to the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system and to the power lock system components through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

REMOTE KEYLESS ENTRY SYSTEM

The Remote Keyless Entry (RKE) system is standard factory-installed equipment on this vehicle. The RKE system includes the following major components, which are described in further detail elsewhere in this service information:

- **Electronic Vehicle Information Center** - The Electronic Vehicle Information Center (EVIC) includes the EVIC switches and the U-Connect Touch™ screen module in the Integrated Center Stack (ICS) located in the center stack area of the instrument panel. (Refer to 08 - Electrical/8M - Message Systems/Message Center/CENTER, Electronic Vehicle Information - Description) .
- **Radio Frequency Hub** - The Radio Frequency Hub (also known as the RF Hub) is the RKE system control module and RF receiver located on the upper liftgate opening header inner reinforcement. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Radio Frequency (RF Hub) - Description).
- **Remote Keyless Entry System Transmitter** - The RKE system transmitter (also known as the FOB with Integrated Key/FOBIK) is the battery powered, wireless and portable Radio Frequency (RF) user controller for all of the features of the RKE system.

These components and their controls are combined to provide the following RKE system features:

- **Customer Programmable Features** - The vehicle operator interfaces with the RF Hub, which is the RKE system controller, using the EVIC. EVIC switches allow the vehicle operator to set or change the RKE system Customer Programmable Features through the U-Connect Touch™ screen module EVIC display.
- **Flash Lights With Lock And Unlock?** - This is a Customer Programmable feature of the RKE system. The first option has the park lamps flash as an optical verification that the RKE system has received a valid **Lock** or **Unlock** request from the FOBIK. The second option disables the optical verification feature.
- **Panic Feature** - In certain markets the FOBIK may also be equipped with a red **Panic** button. Depressing the **Panic** button of the FOBIK while within transmitter range will sound the vehicle signal horn and flash the exterior lighting of the vehicle for about three minutes or until the **Panic** button is depressed a second time, whichever occurs first. Attaining a vehicle speed of about 25.7 kilometers per hour (15 miles per hour) will also cancel the panic event.
- **Programming Additional Transmitters** - Two RKE transmitters are shipped with the vehicle from the factory, but the RKE system can retain the vehicle access codes of up to a total of eight transmitters. The transmitter codes are retained in the RKE system controller memory, even if the battery is disconnected. If a FOBIK is ineffective, lost or an additional FOBIK is desired, new transmitter vehicle access codes can be programmed into the system using a diagnostic scan tool.
- **Remote Liftgate Unlocking** - Depressing the **Liftgate** button of the FOBIK once while within transmitter range will unlock the liftgate of the vehicle.
- **Remote Locking** - Depressing the **Lock** button of the FOBIK while within transmitter range will lock all of the vehicle doors and the liftgate.
- **Remote Engine Start** - On vehicles equipped with the optional Remote Starting System, depressing the **Remote Start** button of the FOBIK twice while within transmitter range will start the engine of the vehicle. Refer to 08 - Electrical/8F - Engine Systems/Starting - Description.
- **Remote Unlocking** - Depressing the **Unlock** button of the FOBIK while within transmitter range will unlock the vehicle and activate the Illuminated Entry System. The specific locks operated and the number of FOBIK button presses required varies depending upon the Customer Programmable settings chosen by the vehicle operator.
- **Remote Unlock Sequence** - This is a Customer Programmable feature of the RKE system. There are two options available. The first option allows only the driver side front door to unlock when the FOBIK **Unlock** button is depressed one time, and the remaining doors unlock when the button is depressed a second time within 5 seconds of the first press. The second option allows all doors and the liftgate to unlock upon a single press of the FOBIK **Unlock** button.
- **Sound Horn On Lock?** - This is a Customer Programmable feature of the RKE system. There are two options available. The first option has the signal horn of the vehicle sound a short chirp as an audible verification that the RKE system received a valid **Lock** request from the FOBIK. The second option disables the audible verification feature.
- **Vehicle Theft Security System Arming** - If the vehicle is equipped with the optional Vehicle Theft Security System (VTSS), depressing the **Lock** button of the FOBIK while within transmitter range will arm the VTSS in addition to activating the remote locking feature. (Refer to 08 - Electrical/8Q - Vehicle Theft Security - Description) .
- **Vehicle Theft Security System Disarming** - If the vehicle is equipped with the optional Vehicle Theft Security System (VTSS), depressing the **Unlock** button of the FOBIK while within transmitter range will disarm the VTSS in addition to activating the remote unlocking feature. (Refer to 08 - Electrical/8Q - Vehicle Theft Security - Description) .

Hard wired circuitry connects many of the RKE system components to the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system and to the RKE system components through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

PASSIVE ENTRY SYSTEM

An optional Passive Entry (PE) system is available factory-installed equipment for this vehicle. The PE system allows this vehicles front doors to be unlocked without the use of a key, as long as an authorized FOB with Integrated Key (FOBIK) is in the possession of, or in close proximity to the individual and the aperture of the vehicle that is to be unlocked. All other features and Customer Programmable feature settings of the power lock system and the Remote Keyless Entry (RKE) system function the same as they would on vehicles without the PE system option.

The PE system includes the following major components, which are described in further detail elsewhere in this service information:

- **Door Handle Switches** - Each PE front door outside handle (also known as a Smart handle) is equipped with three switches and an Integrated Circuit (IC). A tactile **Lock** switch is located on the outer vertical surface of each front door handle grip, a capacitive **Unlock** switch membrane is located on the inner vertical surface of the handle grip, while a Hall effect switch and an IC are concealed within the handle grip.
- **Low Frequency Antennas** - The PE system includes four Low Frequency (LF) antennas, one mounted on the instrument panel support structure below the air conditioning and heater control, one on each rear door hardware module carrier concealed behind the inside trim panel and one at the rearward edge of the cargo area frame beneath the cargo load floor panel at the rear of the vehicle.
- **Radio Frequency Hub** - The Radio Frequency Hub (also known as the RF Hub) is the Passive Entry Keyless Go (PEKG) system control module and RF receiver.

Hard wired circuitry connects many of the PE system components to the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other, to the vehicle electrical system and to the PE system components through the use of a combination of soldered splices, splice block connectors, and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention, as well as pin-out and location views for the various wire harness connectors, splices and grounds.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

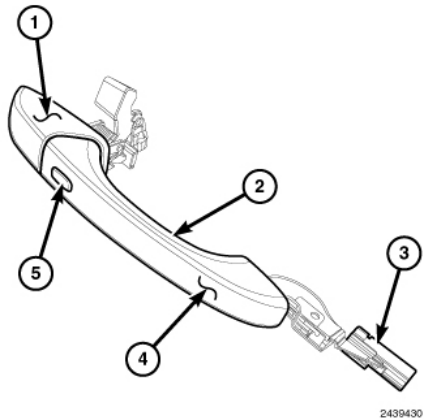
DESCRIPTION

Vehicles equipped with the optional Passive Entry (PE) system have unique outside front door handles that incorporate three switches and a logic circuit. These unique PE door handles are sometimes referred to as smart handles. The handle itself is very similar in appearance to those used in conventional non-PE applications, consisting primarily of a grip (4) and a base (1).

The PE door handles can be readily identified by a tactile, resistive membrane lock switch (5) located on the outward facing vertical surface at the rearward end of the handle grip, and by a capacitive sensor or switch membrane patch on the inside surface (2) of the grip. A third, Hall-effect type switch as well as an Integrated Circuit (IC) chip are concealed within the grip near the handle base.

The mechanical functions and mounting provisions of the PE handle are identical to those of a conventional outside door handle. However, an integral connector receptacle (3) is located at the forward end of the handle grip where it is concealed within the door interior. The PE handle is connected to the vehicle electrical system through a dedicated take out and connector of the PE door jumper wire harness.

The individual switches of the PE outside front door handles cannot be adjusted or repaired. If any one of the switches, the IC or any of the mechanical handle components is damaged or ineffective, the entire handle unit must be replaced. (Refer to 23 - Body/Door - Front/HANDLE - Removal) .



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The three switches of each Passive Entry (PE) outside front door handle are powered by and provide a direct input to the Integrated Circuit (IC) of that door handle. The IC of each PE outside front door handle receives power from the Radio Frequency Hub (also known as the RF Hub) on a signal circuit, and a clean ground from the RF Hub on a return circuit. The PE handle IC and the RF Hub communicate with each other by modulating the current in the signal circuit.

Each PE outside front door handle has three switches. The inputs from those three switches and the handle logic circuit allow each handle to send the RF Hub up to four different signals: Unlock Request, Hall, Lock Request and Error. The RF Hub determines the system response based upon the inputs it receives from each handle as well as the inputs it receives through the authentication process with each detected FOB with Integrated Key (FOBIK).

The tactile, mechanical, resistive membrane lock switch allows the user to actively lock the vehicle. The capacitive switch senses a hand approaching the handle grip to passively unlock the vehicle. The Hall-effect switch senses handle grip movement. An adaptation algorithm in the logic circuit of each handle can modify the sensitivity of the capacitive switches as well as system responses to the Hall-effect switch inputs to compensate for sensed repeated or continuous actuations such as might be caused by the switch membrane being wetted, but restores normal sensitivity about one minute after the repeated or continuous actuation input ceases.

The hard wired inputs and outputs of the PE outside front door handle may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, the most reliable, efficient and accurate means to diagnose this component requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Power operated front door, rear door and liftgate locking mechanisms are standard equipment in this vehicle. The lock mechanisms of each door and liftgate latch are actuated by a reversible electric motor integral to each latch unit. A connector receptacle integral to each latch connects the power lock motor and the integral door or liftgate ajar micro switch to the vehicle electrical system through a dedicated take out and connector of the door or liftgate wire harness.

The power lock motors cannot be adjusted or repaired and, if ineffective or damaged, the entire door or liftgate latch unit must be replaced.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The power lock motors are controlled by outputs received from the Body Control Module (BCM) (also known as the Common Body Controller/CBC). The BCM acts upon programming as well as electronic **lock** or **unlock** command message inputs received over the Controller Area Network (CAN) data bus from the driver or passenger door modules indicating the power lock switch status, or from the Radio Frequency Hub (also known as the RF Hub) based upon inputs from the Remote Keyless Entry (RKE) transmitters or, on vehicles so equipped, from the Passive Entry (PE) system door handle switches.

A positive and negative battery connection to the two lock motor terminals will cause the motor to move in one direction, locking or unlocking the latch. Reversing the current will cause the motor to move in the opposite direction.

The power lock motors and the hard wired circuits between the motors and the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the power lock system or the electronic controls or communication between other modules and devices that provide some features of the power lock system. The most reliable, efficient, and accurate means to diagnose the power lock motors or the electronic controls and communication related to power lock motor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

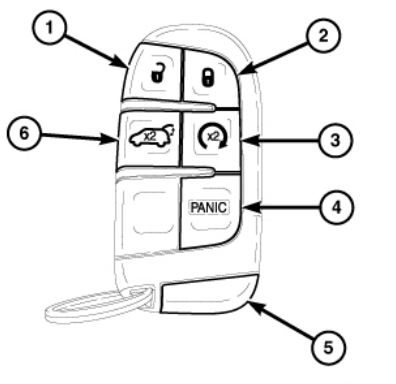
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Vehicles are shipped from the factory with two FOB with Integrated Key (FOBIK) Remote Keyless Entry (RKE) transmitters programmed to the vehicle as standard equipment. The FOBIK circuitry is contained and protected within a molded black plastic case with a black soft rubber touch pad on the face divided into six sections. The rearward end of the FOBIK case houses a mechanical, metal, coded emergency key (5) that is released by sliding a latch button on the back of the FOBIK case.

Depending upon vehicle equipment, each FOBIK has at least three and no more than five functional resistive membrane switches located beneath the six touch pad sections. Each functional touch pad section is clearly identified by white icons or white text and icons identifying the specific function obtained by pushing that button. Domestic market vehicles also include a touch pad section on the FOBIK with the red text **PANIC** applied to it. Not counting the **PANIC** touch pad (4), the available switches include:



- **Unlock (1)** - Standard equipment.
- **Lock (2)** - Standard equipment.
- **Remote Start (3)** - Only for vehicles equipped with the factory-installed remote start system.
- **Liftgate (6)** - Standard equipment.

The FOBIK RKE transmitter is the primary customer active interface for remotely operating the power lock system, the RKE system and the remote start system components and features. However, the FOBIK also has an important passive role in each of the following vehicle systems:

- **Keyless Go System**
- **Passive Entry System**
- **Sentry Key® Theft Deterrent System**
- **Vehicle Theft Security System (VTSS)**

Other than battery replacement, the FOBIK cannot be adjusted or repaired. Once a FOBIK has been programmed to a vehicle, it cannot be reprogrammed for use on any other vehicle. If damaged or ineffective, the FOBIK must be replaced with a new unit. A new and unused FOBIK unit must be properly programmed in order to function properly with the systems of the vehicle. The mechanical emergency key of the new FOBIK must also be cut to match the coding of the lock cylinders in the vehicle.

2014 Dodge JC - DODGE JOURNEY

Fuel Delivery: | **Fuel:**

OPERATION

Special Tools: Click to display a list of tools used in this procedure

The FOB with Integrated Key (FOBIK) incorporates many useful functions into a single, compact unit. The transducer on the internal circuit board of the FOBIK uses low frequency Radio Frequency (RF) communication to ensure vehicle security through an electronic validation or handshake process that is performed with the RF Hub each time the engine is started.

When any one of the Remote Keyless Entry (RKE), liftgate or remote start buttons of the FOBIK is depressed, the on-board transmitter of the FOBIK generates a high frequency RF request signal that is received and validated by the RF Hub. If the RF Hub determines the RF signal was generated by a FOBIK that is valid for the vehicle, the RF Hub relays electronic request messages to the appropriate electronic modules in the vehicle over the Controller Area Network (CAN) data bus to invoke the functions or features associated with the request.

The integrated mechanical emergency key of the FOBIK provides emergency access to the vehicle in case the battery in the vehicle or the transmitter becomes discharged. The emergency key can also be retained to keep any locked on-board vehicle storage compartments such as the glove box secured, for example: While the vehicle is being attended to by a parking valet.

Each vehicle owner is provided with a four-digit Personal Identification Number (PIN) by the dealer at the time of vehicle purchase. This number is required along with a diagnostic scan tool for the dealer to program an additional or replacement FOBIK into the electronics of the vehicle. The emergency key included with a new additional or replacement blank FOBIK must also be cut to match the coding of the lock cylinders in the vehicle.

Diagnosis of a FOBIK transmitter requires the use of a Radio Frequency Detector such as special tool # 9001 . Refer to the appropriate diagnostic information.

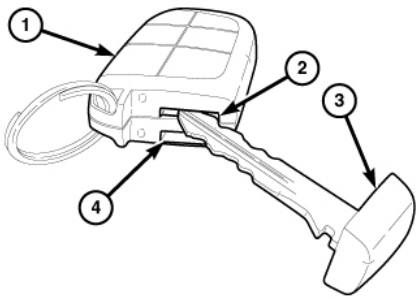
BATTERY REPLACEMENT

CAUTION: **Do not touch or disturb the metal contacts for the battery. Avoid touching the new battery. Battery contamination from oils on your skin may result in shortened battery life. If the battery or contacts are contaminated, clean them thoroughly with rubbing alcohol.**



3068797

1. Unlatch and remove the emergency key (3) from the storage slot (4) of the FOB with Integrated Key (FOBIK) case (1).
2. With the front of the FOBIK case facing upward, insert the tip of the emergency key into the notch (2) between the case halves and twist the key to unsnap and separate the front case half from the back case half.
3. Lift the battery (3) out of the receptacle in the back half of the FOBIK case (2).
4. Replace the battery with a recommended replacement battery. (Refer to 08 - Electrical/8N - Power Systems/Power Locks/TRANSMITTER, Integrated Key FOB - Specifications) .
5. Install the new battery into the receptacle in the back half of the FOBIK case with the negative terminal facing upward.
6. Align the front half of the FOBIK case (1) with the back half.
7. Using hand pressure, squeeze the two FOBIK case halves around their perimeters until they snap back together.
8. Reinsert the emergency key into the storage slot of the FOBIK case.
9. Test the FOBIK operation.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Vehicles equipped with the Passive Entry (PE) system have a unique liftgate handle and light bar unit that incorporates a PE liftgate lock and unlock switch and push button (2). This tactile switch is secured to the underside of the left side of the handle and light bar unit by two latch features (3) integral to the switch housing. The switch button extends through a clearance hole in the handle housing so that it can be accessed on the outer surface of the handle to the left side of center.

A short two-wire pigtail and connector (1) connects the switch to the vehicle electrical system through a dedicated take out and connector of the liftgate wire harness.

The PE liftgate lock and unlock switch cannot be adjusted or repaired. If the switch is damaged or ineffective, the entire switch unit must be replaced.

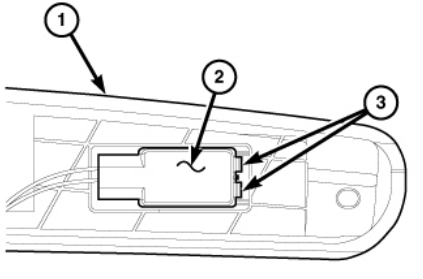
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. With the liftgate lock and unlock switch latch tabs (3) oriented toward the outboard side of the mounting hole, insert switch pigtail wire and connector through the mounting hole from the outside of the handle and light bar unit (1).
2. Engage the fixed locator tabs on the pigtail wire end of the switch (2) above the inboard side of the mounting hole in the handle and light bar unit.
3. While holding the pigtail wire end of the switch firmly against the inboard side of the mounting hole, push the latch tab end of the switch through the mounting hole far enough for the two latch tabs to snap into place above the outboard side of the mounting hole in the handle and light bar unit.



3126517

4. Reinstall the handle and light bar unit onto the liftgate outer panel. (Refer to 23 - Body/Decklid/Hatch/Liftgate/Tailgate/HANDLE, Exterior - Installation) .
5. Reconnect the battery negative cable.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Passive Entry (PE) liftgate lock and unlock switch is a normally open switch that is hard wired to the Radio Frequency Hub (RF Hub) through a signal circuit and a return circuit. The RF Hub continually monitors the condition of the PE liftgate lock and unlock switch and circuits, and will store a Diagnostic Trouble Code (DTC) for any fault that is detected in these circuits.

When the switch button is depressed, it provides a signal to the RF Hub. The RF Hub determines the system response based upon the inputs it receives through the authentication process with each detected FOB with Integrated Key (FOBIK). If the authentication process is successful, the RF Hub sends an electronic **lock request** or **unlock request** message to the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the Controller Area Network (CAN) data bus, and the BCM energizes the liftgate latch lock motor accordingly.

The hard wired circuits between the PE liftgate lock and unlock switch and the RF Hub may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the switch or the electronic controls and communication between other modules and devices that provide some features of the PE system. The most reliable, efficient, and accurate means to diagnose the PE system or the electronic controls and communication related to liftgate lock and unlock switch operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Disconnect and isolate the battery negative cable.
2. Remove the handle and light bar unit (1) from the liftgate outer panel. (Refer to 23 - Body/Decklid /Hatch/Liftgate/Tailgate/HANDLE, Exterior - Removal) .
3. Working from the inside of the handle and light bar unit, depress the two latch features (3) of the liftgate lock and unlock switch (2).
4. While holding the latch features depressed, push the switch out through the outside of the switch mounting hole in the handle and light bar unit.

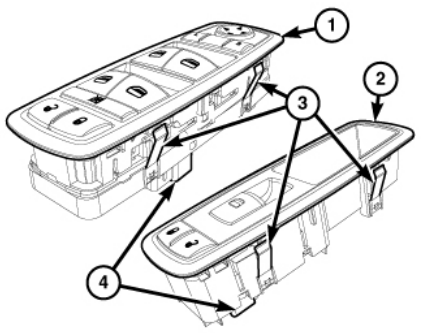
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

A front door power switch module and bezel unit is located near the forward end of the arm rest of each front door trim panel. Two different modules are used: a driver side module (1), and a passenger side module (2). Each switch button in both modules is identified with either an International Control and Display Symbol icon or text that clearly identifies the switch function, and each switch button has a Light Emitting Diode (LED) unit soldered to the switch circuit board that provides back lighting of the icon or text for night visibility.

Each switch module housing is secured within the trim panel armrest by four spring clip retainers (3), two on each side of the switch module housing. The passenger side switch module includes a small cubby bin. A connector receptacle (4) integral to each switch module housing connects the switches to the vehicle electrical system through dedicated take outs and connectors of the door wire harnesses.

The front door power switch modules include the following switches:



2824067

- **Power Lock Switch** - A momentary switch button to control the **Lock** function of the power lock system.
- **Power Unlock Switch** - A momentary switch button to control the **Unlock** function of the power lock system.
- **Power Mirror Selector Switch (Driver Side Switch Only)** - Three mirror selector switch buttons choose the power mirror to be adjusted, **R** (right), **L** (left) or a power fold position (both mirrors).
- **Power Mirror Direction Control Switch (Driver Side Switch Only)** - After a power mirror is selected, pressing down on one of the arrows on the momentary mirror direction switch will move the selected mirror in that direction for as long as it is held down until the limit of the mirror travel is reached.
- **Power Window Lockout Switch (Driver Side Switch Only)** - A latching push-button power window lockout switch allows the vehicle operator to lock out the power window switches on each front and rear passenger door so that those windows may be operated only from the driver side front door master switches. When the lockout switch is engaged, the LED back lighting for each front and rear passenger door power window switch is extinguished.
- **Power Window Switches** - A single two-way, momentary power window switch with a push-to-open and a lift-to-close tab is provide for each passenger door window while the driver side switch module contains four of these power window switches, one switch dedicated to each door window. The switch tab for the driver side front door power window has a second detent in the down direction which is used to activate the **Auto-Down** (also known as express down or one-touch down) feature. A second detent in the up direction on both front door power window switches activates the **Express-Up** feature.

The front door power switch modules cannot be adjusted or repaired. If damaged or ineffective, the entire driver side or passenger side front door switch module must be replaced as a unit.

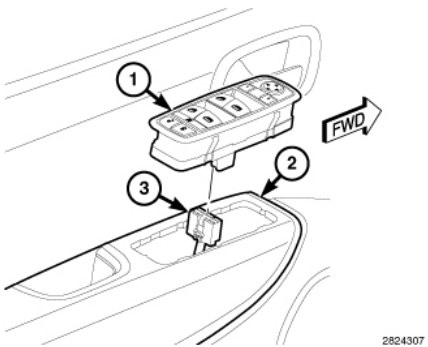
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Position the front door switch module (1) close enough to the mounting hole in the arm rest (2) of the front door trim panel to access and reconnect the front door wire harness connector (3) to the switch connector receptacle.
2. Align the switch module to the arm rest mounting hole.
3. Using hand pressure, press the switch module firmly and evenly into the mounting hole until the four spring steel retainers of the switch are fully engaged and the switch bezel is fully seated against the arm rest.
4. Reconnect the battery negative cable.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

OPERATION

The driver side front door power switch module combines a power lock switch, a power window switch for each of the four door windows including auto-down (also known as one-touch down or express down) and express up features for both front door windows, a power window lockout switch, a power mirror selector switch, and a power mirror adjustment switch in a single unit. The passenger side power door switch module combines a power lock switch and a passenger side front door power window switch with the auto-down and express up features.

The driver side front door power switch module provides resistor multiplexed outputs to the driver door module indicating the power lock switch selection, hard wired analog outputs indicating the power mirror selector switch and adjustment switch selections, and electronic message outputs over a Local Interface Network (LIN) data bus connection indicating the power window switch selections. The passenger side front door power switch module provides resistor multiplexed outputs to the passenger door module indicating both the power lock and power window switch selections.

The hard wired circuits between the driver side front door power switch module and the driver side door module or the rear door power window switches may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between the switch module and the door module or in the diagnosis of the electronic controls and communication between other modules and the door module that provide some features of the power lock, power mirror or power window systems. The most reliable, efficient, and accurate means to diagnose the driver side power switch module or the electronic controls and communication related to power lock, power mirror or power window system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

The hard wired circuits between the passenger side front door power switch module and the passenger side door module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between other modules and the door module that provide some features of the power lock or power window systems. The most reliable, efficient, and accurate means to diagnose the power switch module or the electronic controls and communication related to power lock or power window system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

OPERATION

POWER LOCK SYSTEM

The power lock system uses non-switched battery current received through a fused B(+) fuse in the Body Control Module (BCM) (also known as the Common Body Controller/CBC) so that the system remains operational regardless of the ignition switch position. The BCM is the primary power lock system controller. The power lock switches are hard wired to their respective Driver Door Module (DDM) or Passenger Door Module (PDM). The BCM, the DDM and the PDM all communicate with each other and with other electronic modules in the vehicle over the Controller Area Network (CAN) data bus.

When a door module receives an input from a power lock switch, it sends the appropriate electronic **Lock Request** or **Unlock Request** message to the BCM over the CAN data bus. The BCM responds to these request messages by providing the appropriate outputs to each of the power lock motors to lock or unlock each of the door and liftgate latches. The BCM also stores the power lock system Customer Programmable feature settings received over the CAN data bus from the Electronic Vehicle Information Center (EVIC). The BCM uses these settings and internal programming along with hard wired and electronic message inputs to determine the proper outputs needed to produce each of the appropriate power lock system features.

The power lock system circuits are continually monitored and controlled by the microprocessor and software contained within the BCM, the DDM and the PDM. When one of these modules monitors a problem in any of the power lock system circuits or components, it stores a fault code or Diagnostic Trouble Code (DTC) in its memory circuit. The hard wired circuits between components related to the power lock system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the power lock system or the electronic controls or communication between other modules and devices that provide features of the power lock system. The most reliable, efficient, and accurate means to diagnose the power lock system or the electronic controls and communication related to power lock system operation, as well as the retrieval or erasure of a DTC requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

REMOTE KEYLESS ENTRY SYSTEM

The Remote Keyless Entry (RKE) system uses non-switched battery current received through a fused B(+) fuse in the Body Control Module (BCM) (also known as the Common Body Controller/CBC) so that the system remains operational regardless of the ignition switch position. The Radio Frequency Hub (also known as the RF Hub) is the primary RKE system controller as well as the Radio Frequency (RF) RKE receiver. The RF Hub validates the vehicle access code of each RKE transmitter (also known as FOB with Integrated Key/FOBIK) from which it receives RF signal inputs. It ignores requests from any transmitter for which it has no stored vehicle access code.

The RF Hub communicates and shares resources with the BCM and many other electronic modules in the vehicle over the CAN data bus. The RF Hub also stores the RKE system Customer Programmable feature settings received over the CAN data bus from the Electronic Vehicle Information Center (EVIC). When the RF Hub receives an input from a valid transmitter source, it uses these settings and internal programming to send the appropriate electronic request messages to the BCM and other electronic modules over the CAN data bus to invoke the proper RKE system features and responses.

The RKE system circuits and transmitter inputs are continually monitored by the microprocessor and software contained within the RF Hub. When the RF Hub monitors a problem in any of the RKE system circuits or transmitters, it stores a Diagnostic Trouble Code (DTC) in its memory circuit. The hard wired circuits between components related to the RKE system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the RKE system or the electronic controls or communication between other modules and devices that provide features of the RKE system. The most reliable, efficient, and accurate means to diagnose the RKE system or the electronic controls and communication related to RKE system operation, as well as the retrieval or erasure of a DTC requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

PASSIVE ENTRY SYSTEM

In the Passive Entry (PE) system the doors and the liftgate are unlocked passively; however, they must still be locked actively after exiting the vehicle using the tactile **Lock** button on either front door handle or the liftgate handle and light bar unit. When the system senses a hand approaching the capacitive switch in the door handle grip or detects a button press of the liftgate **Lock** and **Unlock** switch, it sends out challenge messages through the Low Frequency (LF) antennas to authenticate the presence and location of a valid FOB with Integrated Key (FOBIK).

The FOBIK responds by sending a Very High Frequency (VHF) message back to the receiver within the Radio Frequency Hub (also known as the RF Hub). If the RF Hub determines the FOBIK is valid and that it is located outside the vehicle in the same zone or vicinity as the door handle or liftgate switch being activated, it sends an electronic**Unlock Request** message over the Controller Area Network (CAN) data bus to the Body Control Module (BCM) (also known as the Common Body Controller/CBC) to automatically unlock and allow entry to that door.

The PE system circuits and FOBIK inputs are continually monitored by the microprocessor and software contained within the RF Hub. When the RF Hub monitors a problem in any of the PE system circuits or FOBIK inputs, it stores a Diagnostic Trouble Code (DTC) in its memory circuit. The hard wired circuits between components related to the PE system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin-out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the PE system or the electronic controls or communication between other modules and devices that provide features of the PE system. The most reliable, efficient, and accurate means to diagnose the PE system or the electronic controls and communication related to PE system operation, as well as the retrieval or erasure of a DTC requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

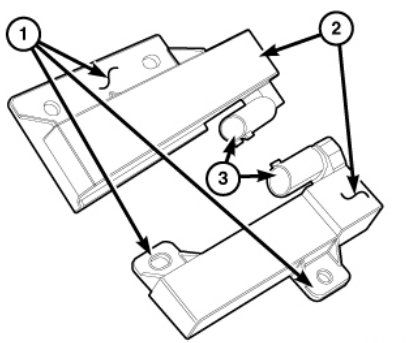
DESCRIPTION

Vehicles equipped with the optional Passive Entry (PE) and Keyless Go (KG) systems have several Low Frequency (LF), ferrite antenna units (2) located within the vehicle. Each ferrite PE antenna unit is contained within a molded black plastic housing with an integral connector receptacle (3) molded into one end. The connector receptacle contains terminal pins that connect the antenna to the vehicle electrical system through a twisted pair of conductors and a connector that are part of the adjacent body or instrument panel wire harness.

Each antenna housing also includes an integral mounting flange or flanges (1) which can be used to mount the unit with screws. This vehicle platform uses five PE antenna units. One is secured to the outside of the liftgate opening lower cross member concealed by the rear fascia, one is secured to each rear door inner panel concealed by the inside door trim panels, one is secured to the rear floor panel cross member just forward of the cargo or third row seating area and one is located on the underside of the shifter bracket beneath the center floor console.

The antennas are each connected to the Radio Frequency Hub (also known as the RF Hub) on dedicated and sequentially numbered circuits. The left rear door antenna is connected through the antenna 1 circuits, the right rear door antenna is connected through the antenna 2 circuits, the cargo or third row seating area antenna is connected through the antenna 3 circuits, the center floor console area antenna is connected through the antenna 4 circuits and the liftgate opening antenna is connected through the antenna 5 circuits.



JC LOW FREQUENCY ANTENNA AND CIRCUIT NUMBERING	
Location	Antenna And Circuit Number
Left Rear Door	1
Right Rear Door	2
Cargo or Third Row Seating Area	3
Center Floor Console Area	4
Liftgate Opening	5

An LF antenna unit cannot be adjusted or repaired. If ineffective or damaged, it must be replaced with a new unit. For applications where it is used, the antenna unit adapter or retainer may be serviced only as a unit with the LF antenna.

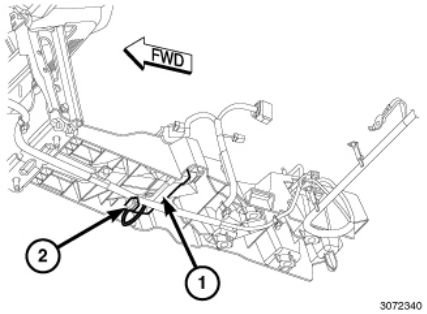
CENTER FLOOR CONSOLE

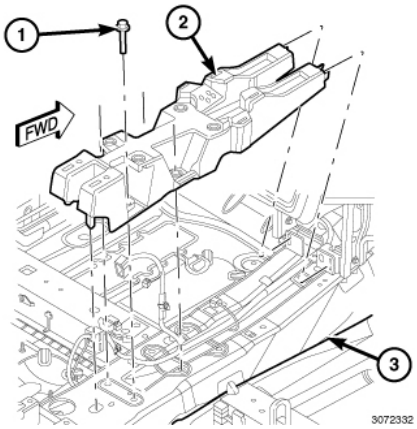
Labor Operations: Click to display a list of Labor Operations associated with this procedure

AUTOMATIC TRANSMISSION

1. Position the Low Frequency (LF) antenna (1) to the underside of the console floor shift bracket.
2. Install and tighten the two screws that secure the LF antenna to the underside of the shift bracket. Tighten the screws securely.
3. Position the shift bracket close enough to the floor panel transmission tunnel to access and reconnect the wire harness connector (2) to the connector receptacle for the LF antenna.



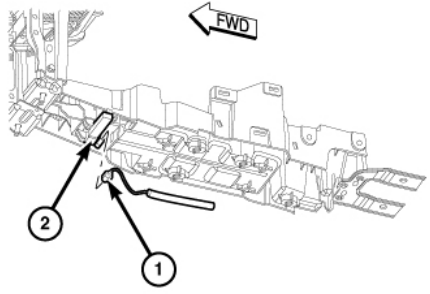
4. Engage the alignment pin and the two snap clips at the front of the shift bracket (2) into the holes in the instrument panel center support bracket, then lower the rear of the shift bracket far enough to engage the alignment pin into the hole in the floor panel transmission tunnel (3).
5. Install and tighten the four screws (1) that secure the shift bracket to the tunnel. Tighten the screws to 8 N·m (71 in. lbs.).
6. Reinstall the automatic transmission floor shift assembly onto the shift bracket. Refer to 21 - Transaxle for the procedures covering the transaxle model and shifter type found in the vehicle.
7. Reconnect the battery negative cable.



MANUAL TRANSMISSION

1. Position the Low Frequency (LF) antenna (2) to the underside of the console floor shift bracket.
2. Install and tighten the two screws that secure the LF antenna to the underside of the shift bracket. Tighten the screws securely.

3. Position the shift bracket close enough to the floor panel transmission tunnel to access and reconnect the wire harness connector (1) to the connector receptacle for the LF antenna.

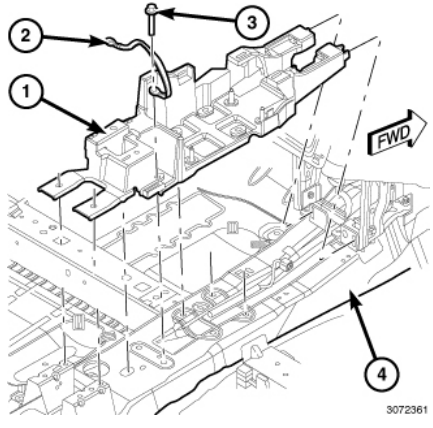


4. Engage the alignment pin and the two snap clips at the front of the shift bracket (1) into the holes in the instrument panel center support bracket, then lower the rear of the shift bracket far enough to engage the alignment pin into the hole in the floor panel transmission tunnel (4).

5. Position the ground strap (2) to the shift bracket mounting hole.

6. Install and tighten the four screws (3) that secure the shift bracket to the tunnel. Tighten the screws to 8 N·m (71 in. lbs.).

7. Reinstall the manual transmission floor shift assembly onto the shift bracket. Refer to 21 - Transaxle for the procedures covering the transaxle model and shifter type found in the vehicle.



8. Reconnect the battery negative cable.

OPERATION

The Passive Entry (PE) antenna units allow the transmitter within the Radio Frequency Hub (also known as the RF Hub) to communicate via Low Frequency (LF) radio transmission with a FOB with Integrated Key (FOBIK) that is located inside the vehicle or, at most, about 2 meters (6.5 feet) horizontally in all directions around the outside of the vehicle. The RF Hub uses communication through the antenna units to wake up and challenge a FOBIK that is within range in order to authenticate whether that FOBIK is valid (programmed) to the vehicle. The RF Hub communication with the FOBIK is on 20 kilohertz using Frequency-Shift Keying (FSK) modulation.

Each antenna unit has two dedicated connections to the RF Hub. One connection is the LF antenna output circuit, while the other connection Is the LF antenna return circuit. These circuits to each antenna unit are a twisted pair to help reduce the potential for induced electrical interference. The RF Hub microprocessor continuously monitors all of the antenna units and will store a Diagnostic Trouble Code (DTC) for any fault that it detects.

The hard wired inputs and outputs of the antenna units may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, the most reliable, efficient, and accurate means to diagnose the antenna units requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

SENTRY KEY IMMOBILIZER SYSTEM

The Sentry Key Immobilizer System (SKIS) is factory-installed standard equipment on this model. The SKIS provides passive vehicle protection, immobilizing the vehicle by preventing the engine from operating unless a valid electronically encoded key or FOB with Integrated Key (FOBIK) is detected. In vehicles not equipped with the Passive Entry Keyless Go (PEKG) system, a valid encoded key or FOBIK must be present within the Keyless Ignition Node (KIN) (also known as the IGnition Node Module/IGNM) for the engine to continue to operate. In vehicles equipped with the PEKG system, the FOBIK must only be present somewhere within the passenger compartment of the vehicle for the engine to continue to operate.

The SKIS used in combination with the export premium version of the Vehicle Theft Alarm (VTA) adds a steering shaft lock feature that provides passive protection by preventing the vehicle from being steered unless a valid encoded key or FOBIK is present within the KIN (without PEKG), or a valid FOBIK is present somewhere within the passenger compartment of the vehicle (with PEKG). The export premium version of the VTA is only available in vehicles manufactured for sale in certain markets where it is required equipment.

The SKIS includes the following major components, which are described in further detail elsewhere in this service information:

- **Keyless Ignition Node** - The Keyless Ignition Node (KIN) (also known as the IGnition Node Module/IGNM) is located in the instrument panel just inboard of the steering column. (Refer to 08 - Electrical/8E - Electronic Control Modules/RECEIVER, Keyless Ignition Node/Description) .
- **Low Frequency Antenna** - Vehicles equipped with the optional Passive Entry Keyless Go (PEKG) system have several low frequency antenna units strategically placed within the vehicle.
- **Powertrain Control Module** - The Powertrain Control Module (PCM) (also known as the Engine Control Module/ECM) is located in the engine compartment. The PCM provides the SKIS engine control logic. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Powertrain Control - Description) .
- **Radio Frequency Hub Module** - The Radio Frequency Hub Module (RFHM) (also known as the RF Hub) is located above the headliner at the liftgate opening. The RFHM is hard wired to the Keyless Ignition Node (KIN). The RFHM performs the functions previously performed by a Wireless Control Module (WCM) (also known as the Sentry Key REmote Entry Module/SKREEM or the Sentry Key Immobilizer Module/SKIM), a Wireless Ignition Node (WIN) and a Passive Entry Module (PEM). (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Radio Frequency (RF Hub) /Description).
- **Security Indicator** - A security indicator is integral to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC). (Refer to 08 - Electrical/8J - Instrument Cluster/Description) .
- **Sentry Key Transponder** - A Sentry Key transponder microchip is located within each key or FOB with Integrated Key (FOBIK), which also includes an integral Remote Keyless Entry (RKE) transmitter and an integral mechanical valet key. (Refer to 08 - Electrical/8Q - Vehicle Theft Security/KEY, Transponder - Description) .
- **Shaft Lock Module** - A shaft lock module (also known as the Electronic Steering Column Lock/ESCL module) is located on the lower end of the steering column below the instrument panel in the passenger compartment of vehicles built for sale in certain export markets and equipped with the export premium version of the VTA where it is required equipment.

The PCM and the RFHM each contain a microcontroller and programming that allow them to communicate with each other and other electronic modules in the vehicle using the Controller Area Network (CAN) data bus. In addition, the KIN, the RFHM and the shaft lock module communicate with each other using a Local Interface Network data bus. (Refer to 08 - Electrical/8E - Electronic Control Modules/COMMUNICATION - Description) .

Hard wired circuitry connects the various SKIS system components to each other through the electrical system of the vehicle. These hard wired circuits are integral to several wire harnesses, which are routed throughout the vehicle and retained by many different methods. These circuits may be connected to each other and to the vehicle electrical system through the use of a combination of soldered splices, splice block connectors and many different types of wire harness terminal connectors and insulators. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, further details on wire harness routing and retention as well as pin out and location views for the various wire harness connectors, splices and grounds.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

SENTRY KEY IMMOBILIZER SYSTEM

The Sentry Key Immobilizer System (SKIS) is designed to provide passive protection against unauthorized vehicle use by disabling the engine whenever any method other than a valid FOBIK is used to start the vehicle. The SKIS is considered a passive protection system, because it is always active when the ignition system is energized and it does not require any customer intervention. The SKIS uses Low Frequency (LF) communication to obtain confirmation that the FOBIK in the interior of the vehicle is valid for operating the vehicle. The microprocessor-based SKIS hardware and software also uses electronic messages to communicate with other electronic modules in the vehicle over the Controller Area Network (CAN) data bus. (Refer to 08 - Electrical/8E - Electronic Control Modules/COMMUNICATION - Operation) .

Two pre-programmed FOBIK transponders are provided with the vehicle from the factory. Each RF-Hub will recognize a maximum of eight FOBIK transponders. If the customer would like additional FOBIKs, other than those provided with the vehicle, they may be purchased from any authorized dealer. These additional FOBIKs must be programmed to the RF-Hub in the vehicle in order for the system to recognize them as valid. This can be done by the dealer using a diagnostic scan tool. All FOBIKs used on that particular vehicle must be in the vehicle when programming takes place. (Refer to 08 - Electrical/8Q - Vehicle Theft Security - Standard Procedure) .

The RF Hub performs a self-test of the SKIS each time the ignition is pressed to the ON position, and will store fault information in the form of a Diagnostic Trouble Code (DTC) if a system malfunction is detected. The WIN will also send an electronic message to the instrument cluster if a fault is detected, and the instrument cluster illuminates the security indicator.

The hard wired circuits between components related to the SKIS may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, procedures for proper wire and connector repair, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the SKIS or the electronic controls and communication between other modules and devices that provide some features of the SKIS. The most reliable, efficient and accurate means to diagnose the SKIS or the electronic controls and communication related to SKIS operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information for any Diagnostic Trouble Code (DTC) procedures.

For any Body Control Module DTC: (Refer to 28 - DTC-Based Diagnostics/MODULE, Body Control (BCM) - Diagnosis and Testing).

For any Radio Frequency Hub DTC: (Refer to 28 - DTC-Based Diagnostics/MODULE, Radio Frequency (RF Hub) - Diagnosis and Testing).

For any Powertrain Control Module DTC: (Refer to 28 - DTC-Based Diagnostics/MODULE, Powertrain Control (PCM) - Diagnosis and Testing).

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The functions and features of the Sentry Key Immobilizer Module (SKIM) (also previously known as the Sentry Key REmote Entry Module/SKREEM, the Wireless Control Module/WCM or the Wireless Ignition Node/WIN) are all integral to the Radio Frequency Hub Module (RFHM) (also known as the RF Hub) and the Keyless Ignition Node (KIN) (also known as the IGnition Node Module/IGNM) in this vehicle.

The RFHM is the primary component of the Sentry Key Immobilizer System (SKIS). It is also the receiver for the Remote Keyless Entry (RKE) system and the Tire Pressure Monitor (TPM) system. The RFHM is located on the upper liftgate opening reinforcement near the back of the vehicle, where it is concealed above the headliner trim. (Refer to 08 - Electrical/8E - Electronic Control Modules/MODULE, Radio Frequency (RF Hub) /Description).

The KIN includes the integral ignition switch push button. The KIN is located in the instrument panel, just to the right of the steering column. The remainder of the KIN including its mounting provisions and electrical connections are concealed within the instrument panel. (Refer to 08 - Electrical/8E - Electronic Control Modules/RECEIVER, Keyless Ignition Node/Description) .

Fuel Delivery: | **Fuel:**

OPERATION

The functions and features of the Sentry Key Immobilizer Module (SKIM) (also previously known as the Sentry Key REmote Entry Module/SKREEM, the Wireless Control Module/WCM or the Wireless Ignition Node/WIN) are all integral to the Radio Frequency Hub Module (RFHM) (also known as the RF Hub) and the Keyless Ignition Node (KIN) (also known as the IGnition Node Module/IGNM) in this vehicle. The RFHM contains a Radio Frequency (RF) transceiver and a microcontroller. The RFHM transmits Low Frequency (LF) signals to, and receives LF signals from the Sentry Key transponder integral to the FOB with Integrated Key (FOBIK) through a tuned antenna internal to the RFHM housing. The KIN allows the vehicle operator to select and monitor the status of the ignition switch and also transmits the selected ignition switch status to the RFHM.

The RFHM also serves as the Remote Keyless Entry (RKE) RF receiver and, if the vehicle is so equipped, the receiver for the Tire Pressure Monitoring (TPM) system. (Refer to 08 - Electrical/8N - Power Systems/Power Locks - Description) or (Refer to 22 - Tires and Wheels/Tire Pressure Monitoring - Description) . The RFHM communicates over the Controller Area Network (CAN) data bus with the Body Control Module (BCM) (also known as the Common Body Controller/CBC), the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC), the Powertrain Control Module (PCM) (also known as the Engine Control Module/ECM) or the diagnostic scan tool. It also communicates over a dedicated Local Interface Network (LIN) data bus circuit with the KIN.

The RFHM and the PCM both use software that includes a rolling code algorithm strategy, which helps to reduce the possibility of unauthorized Sentry Key Immobilizer System (SKIS) disarming. The rolling code algorithm ensures security by preventing an override of the SKIS through the unauthorized substitution of the RFHM or the PCM. However, the use of this strategy also means that replacement of either the RFHM or the PCM units will require a system initialization procedure to restore system operation.

The RFHM retains in memory the ID numbers of any Sentry Key FOBIK transponder that is programmed into it. A maximum of eight Sentry Key FOBIK transponders can be programmed into the RFHM. For added system security, each RFHM is programmed with a unique Secret Key code. This code is stored in memory, sent over the CAN data bus to the PCM, and is encoded to the transponder of every Sentry Key FOBIK that is programmed into the RFHM. Therefore, the Secret Key code is a common element that is found in every component of the SKIS.

Another security code called a PIN is used to gain access to the RFHM Secured Access Mode. The Secured Access Mode is required during service to perform the SKIS initialization and Sentry Key FOBIK transponder programming procedures. The RFHM also stores the Vehicle Identification Number (VIN) in its memory, which it learns through a CAN data bus message from the PCM during SKIS initialization.

In the event that a RFHM replacement is required, the Secret Key code can be transferred to the new RFHM from the PCM using the diagnostic scan tool and the SKIS initialization procedure. Proper completion of the SKIS initialization will allow the existing Sentry Key FOBIK units to be programmed into the new RFHM so that new FOBIK units will not be required. In the event that the original Secret Key code cannot be recovered, RFHM replacement will also require new Sentry Key FOBIK units. The diagnostic scan tool will alert the technician during the SKIS initialization procedure if new Sentry Key FOBIK units are required. (Refer to 08 - Electrical/8E - Electronic Control Modules - Standard Procedure) .

When the status of the ignition switch transitions to On, the RFHM transmits a LF signal to excite the transponder in the FOBIK. The RFHM then waits for a LF signal response from the transponder. If the response received identifies the FOBIK as valid, the RFHM sends an electronic **valid key** message to the PCM over the CAN data bus. If the response received identifies the FOBIK as invalid or if no response is received from the FOBIK transponder, the RFHM sends an **invalid key** message to the PCM. The PCM will enable or disable engine operation based upon the status of the RFHM messages. It is important to note that the default condition in the PCM is an **invalid key**; therefore, if no message is received from the RFHM by the PCM, the engine will be disabled and the vehicle immobilized after two seconds of running.

The RFHM also sends electronic **security indicator** request messages to the IC over the CAN data bus to tell the IC how to operate the security indicator. The **security indicator** request message from the RFHM tells the IC to turn the indicator On for about three seconds each time the status of the ignition switch transitions to On as a bulb test. After completion of the bulb test, the RFHM sends **security indicator** request messages to the IC to turn the indicator Off, turn the indicator On or to flash the indicator On and Off. If the security indicator flashes or stays On solid after the bulb test, it signifies a SKIS fault. If the RFHM detects a system malfunction or the SKIS has become ineffective, the security indicator will stay On solid. If the RFHM detects an invalid FOBIK or if a FOBIK transponder-related fault exists, the security indicator will flash.

The SKIS performs a self-test each time the status of the ignition switch transitions to On, and will store fault information in the form of a Diagnostic Trouble Code (DTC) in RFHM memory if a system malfunction is detected. The hard wired circuits of the RFHM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the RFHM or the electronic controls and communication between other modules and devices that provide some features of the SKIS. The most reliable, efficient and accurate means to diagnose the RFHM or the electronic controls and communication related to RFHM operation requires the use of a diagnostic scan tool.

INSTALLATION

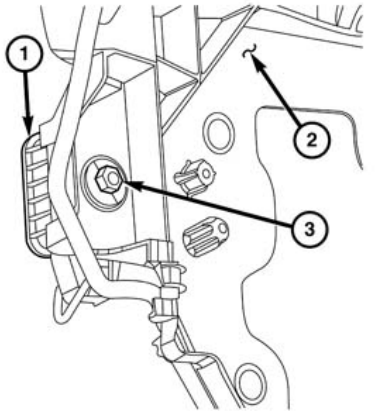
Labor Operations: Click to display a list of Labor Operations associated with this procedure

1.

2. Position the siren (1) to the face of the Front End Module (FEM) carrier (2) below the left front lamp unit.

3. Install the washer over the stud of the siren on the engine compartment side of the FEM carrier.

4. Install and tighten the nut (3) that secures the siren to the engine compartment side of the FEM carrier. Tighten the nut to 5 N·m (44 in. lbs.).

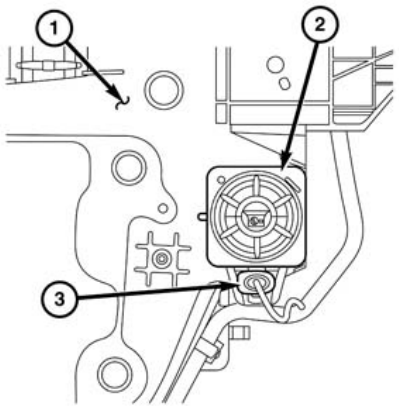


0831010865

5. Reconnect the FEM wire harness connector (3) to the connector receptacle of the siren (2) on the face of the FEM carrier (1).

6. Reinstall the front bumper fascia onto the vehicle. (Refer to 13 - Frame and Bumpers/Bumpers/FASCIA, Front - Installation) .

7. Reconnect the negative cable to the battery.



0831010866

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The microcontroller within the alarm siren module provides the siren unit features and functions based upon internal programming and electronic **arm** and **disarm** messages received from the Intrusion Transceiver Module (ITM) over a dedicated serial bus communication circuit. The siren module receives battery voltage on a fused B(+) circuit through a fuse in the Body Control Module (BCM) (also known as the Common Body Controller/CBC) and receives a path to ground through a ground circuit in the Front End Module (FEM) wire harness. These connections allow the siren to remain operational, regardless of the status of the ignition switch.

When the premium version of the Vehicle Theft Alarm (VTA) is armed, the siren module continuously monitors electronic message inputs from the BCM to sound its internal siren. While armed, the siren also enters its auto-detect mode. While in the auto-detect mode, if the siren module detects that its power supply or communication circuits are being tampered with or have been sabotaged, it will sound an audible alarm and continue to operate through an on-board backup battery. If the siren module is in its disarmed mode when its power supply or communication circuits are interrupted, the siren will not sound.

The alarm siren module will also notify the BCM when the backup battery requires charging, and the BCM will send electronic messages that will allow the backup battery to be recharged through the battery voltage and ground circuits to the alarm siren module only while the status of the ignition switch is On and the engine is running. This prevents the potential discharge of the main battery while the vehicle is not being operated.

The alarm siren module will self-detect problems with its internal and external power supply and communication circuits, then send electronic messages indicating the problem to the BCM upon receiving an **arm** or **disarm** request message. The BCM will store a Diagnostic Trouble Code (DTC) for any detected alarm siren module fault. The DTC can then be retrieved with a diagnostic scan tool through the 16-way Data Link Connector (DLC) located under the driver side lower edge of the instrument panel over the Controller Area Network (CAN) data bus.

The hard wired inputs and outputs for the alarm siren module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the alarm siren module or the electronic controls and communication between other modules and devices that provide some features of the VTA system. The most reliable, efficient and accurate means to diagnose the alarm siren module or the electronic controls and communication related to alarm siren module operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

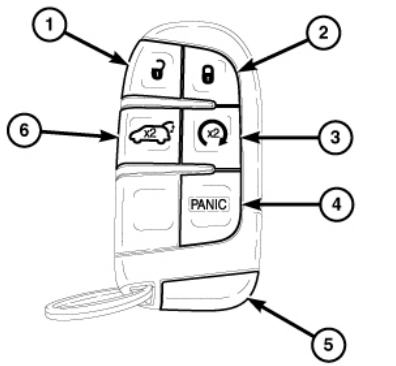
DESCRIPTION

Vehicles are shipped from the factory with two FOB with Integrated Key (FOBIK) Remote Keyless Entry (RKE) transmitters programmed to the vehicle as standard equipment. The FOBIK circuitry is contained and protected within a molded black plastic case with a black soft rubber touch pad on the face divided into six sections. The rearward end of the FOBIK case houses a mechanical, metal, coded emergency key (5) that is released by sliding a latch button on the back of the FOBIK case.

Depending upon vehicle equipment, each FOBIK has at least three and no more than five functional resistive membrane switches located beneath the six touch pad sections. Each functional touch pad section is clearly identified by white icons or white text and icons identifying the specific function obtained by pushing that button. Domestic market vehicles also include a touch pad section on the FOBIK with the red text **PANIC** applied to it. Not counting the **PANIC** touch pad (4), the available switches include:



3068587

- **Unlock (1)** - Standard equipment.
- **Lock (2)** - Standard equipment.
- **Remote Start (3)** - Only for vehicles equipped with the factory-installed remote start system.
- **Liftgate/Deck Lid (6)** - Standard equipment.

The FOBIK RKE transmitter is the primary customer active interface for remotely operating the power lock system, the RKE system, and the remote start system components and features. However, the FOBIK also has an important passive role in each of the following vehicle systems:

- **Keyless Go System**
- **Passive Entry System**
- **Sentry Key® Theft Deterrent System**
- **Vehicle Theft Security System (VTSS)**

Other than battery replacement, the FOBIK cannot be adjusted or repaired. If damaged or ineffective, the FOBIK must be replaced with a new unit. A new and unused FOBIK unit must be properly programmed in order to function properly with the systems of the vehicle. The mechanical emergency key of the new FOBIK must also be cut to match the coding of the lock cylinders in the vehicle.

Programming A FOBIK - For FOBIK programming, (Refer to 08 - Electrical/8E - Electronic Control Modules - Standard Procedure) .

OPERATION

Special Tools: Click to display a list of tools used in this procedure

The FOB with Integrated Key (FOBIK) incorporates many useful functions into a single, compact unit. The transducer on the internal circuit board of the FOBIK uses low frequency Radio Frequency (RF) communication to ensure vehicle security through an electronic validation or handshake process that is performed with the Radio Frequency Hub (RF Hub) each time the engine is started.

When any one of the Remote Keyless Entry (RKE), liftgate/deck lid or remote start buttons of the FOBIK is depressed, the on-board transmitter of the FOBIK generates a high frequency RF request signal that is received and validated by the RF Hub. If the RF Hub determines the RF signal was generated by a FOBIK that is valid for the vehicle, the RF Hub relays electronic request messages to the appropriate electronic modules in the vehicle over the Controller Area Network (CAN) data bus to invoke the functions or features associated with the request.

Each vehicle owner is provided with a four-digit Personal Identification Number (PIN) by the dealer at the time of vehicle purchase. This number is required along with a diagnostic scan tool for the dealer to program an additional or replacement FOBIK into the electronics of the vehicle. The emergency key included with a new additional or replacement blank FOBIK must also be cut to match the coding of the lock cylinders in the vehicle.

Diagnosis of a FOBIK transmitter requires the use of a Radio Frequency Detector such as: 9001 or Analyzer, TPM/RKE CH9936 . Refer to the appropriate diagnostic information. (Refer to 28 - DTC-Based Diagnostics/MODULE, Radio Frequency (RF Hub) - Diagnosis and Testing).

EMERGENCY STARTING

The integrated mechanical key of the FOBIK provides emergency access to the vehicle in case the battery in the vehicle or the transmitter becomes discharged.

In the event that the battery in the FOBIK is low or there is a Low Frequency Antenna problem:

- Hold the FOBIK with the key ring away from the Keyless Ignition Node (KIN).
- With the **Lock/Unlock** button end of the FOBIK, press the Start/Stop Button (SSB) of the Keyless Ignition Node (KIN) switch.
- Push gently to prevent scratching the surface of the SSB in the KIN.

Programming FOBIKs For FOBIK Programming, (Refer to 08 - Electrical/8E - Electronic Control Modules - Standard Procedure) .

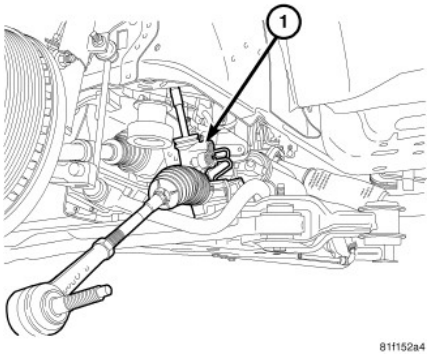
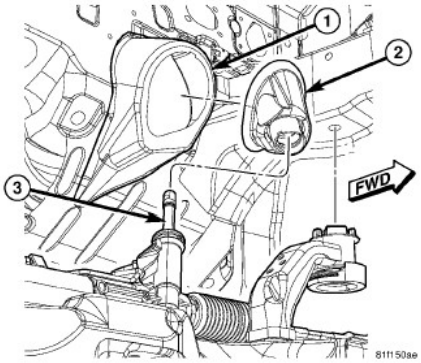
LEFT HAND DRIVE - FWD

Labor Operations: Click to display a list of Labor Operations associated with this procedure

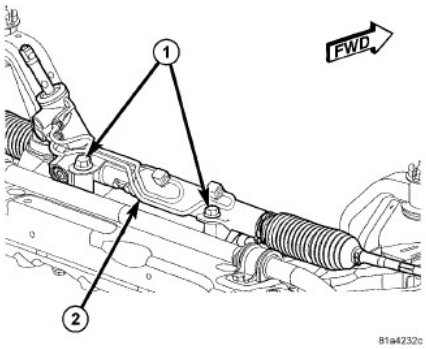
1. If necessary, install the outer tie rods onto the inner tie rod threads. As the outer tie rods are installed, count out same number of rotations as were counted on tie rod removal. This will get the toe setting somewhat close to specification before the vehicle is aligned at the end of this procedure. Snug the tie rod jam nuts on both ends of gear. Tighten the tie rod jam nuts to specification while performing the wheel alignment at the end of this procedure.
2. Carefully install the steering gear (1) through the left wheel opening using the reverse of how it was removed. Move it across the crossmember until centered.



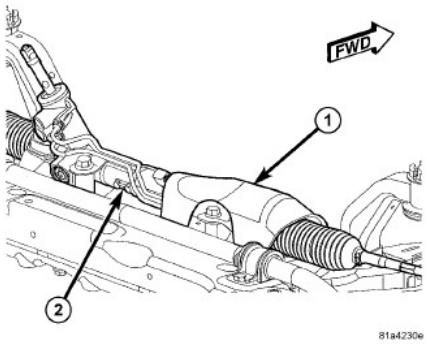
3. Tip the steering gear pinion shaft (3) straight up and install the dash seal (2) matching it to the contour of the steering gear housing.



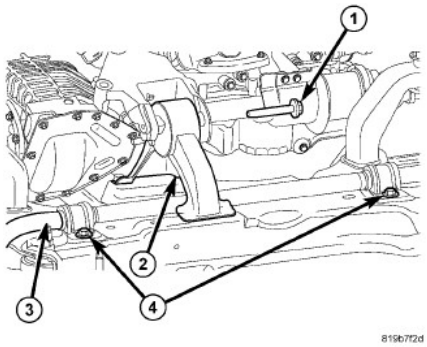
4. Position the steering gear in mounted position on the crossmember.
5. Install the two bolts (1) securing the steering gear (2) to the crossmember. Tighten the gear mounting bolts to 115 N·m (85 ft. lbs.).



6. Install the heat shield (1) over the steering gear (2). Install the mounting screws and push-pins. Tighten the screws to 6 N·m (53 in. lbs.).



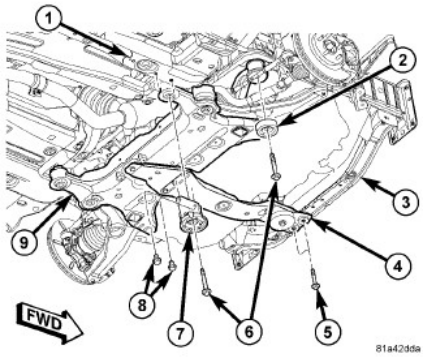
7. Install the rear isolator (1) to the crossmember.
8. Install the four mounting bolts that hold the rear isolator to the crossmember and tighten to 50 N·m (37 ft. lbs.).
9. Install the rear engine mount through-bolt (1). (Refer to 09 - Engine/Engine Mounting/INSULATOR, Engine Mount - Installation)



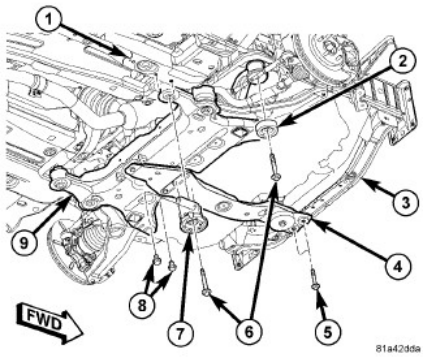
10. Center the power steering gear rack in its travel as necessary.

NOTE: When installing the front suspension crossmember (1) it is very important that the crossmember be attached to the body in exactly the same spot as when it was removed. Otherwise, the vehicle's wheel alignment settings (caster and camber) will be lost making wheel alignment more difficult.

11. Slowly raise the crossmember (9) into mounted position using the transmission jack matching the crossmember to the marked locations on the body made during removal.

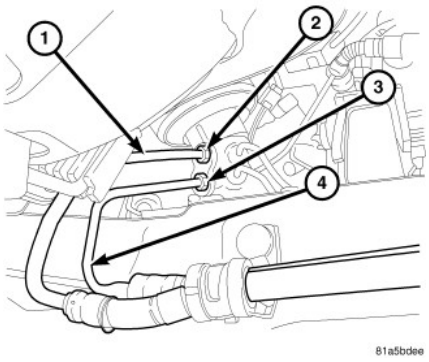


12. Position the front crossmember reinforcement brackets (7) (one each side of vehicle) over the crossmember rear mounting bushings and install the mounting screws (8), but do not tighten at this time.
13. Install the four mounting bolts (6) securing the front crossmember (1) to the body. Tighten the crossmember mounting bolts to 135 N·m (100 ft. lbs.).
14. Tighten the crossmember reinforcement bracket mounting screws (8) to 50 N·m (37 ft. lbs.).
15. Remove the transmission jack.

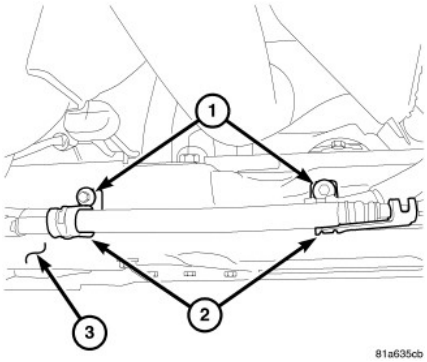


16. Install the pressure hose tube (4) at the gear. Tighten the tube nut (3) to 32 N·m (24 ft. lbs.).

17. Install the return hose tube (1) at the gear. Tighten the tube nut (2) to 32 N·m (24 ft. lbs.).



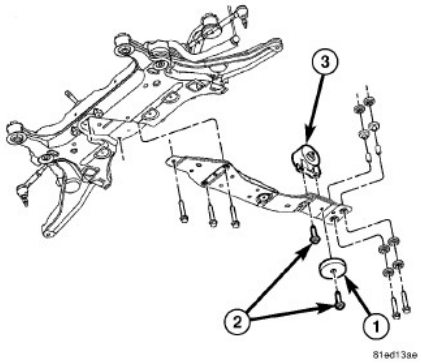
18. Position the power steering hose routing clamps (2) on the crossmember. Install and tighten the screws to 8 N·m (71 in. lbs.).



19. Position the fore-aft crossmember in the engine compartment and install the mounting bolts.

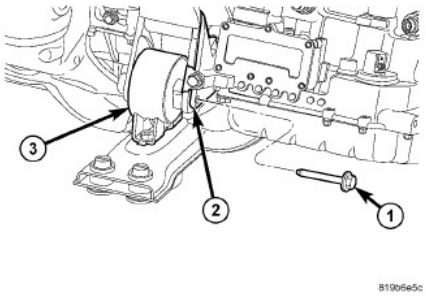
20. Tighten the forward mounting bolts at the radiator support to 55 N·m (41 ft. lbs.).

21. Tighten the rearward mounting bolts at the suspension crossmember to 55 N·m (41 ft. lbs.).



22. Install the front engine mount through-bolt (1) and tighten to 60 N·m (44 ft. lbs.).

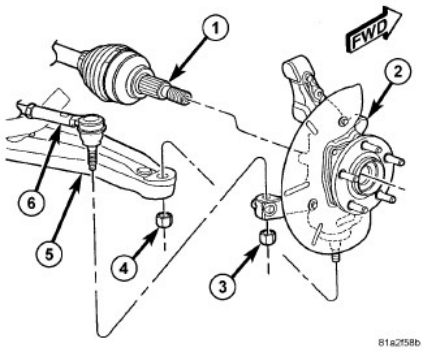
23. If equipped, install the engine belly pan.



NOTE: Prior to attaching the outer tie rod end to the knuckle, inspect the tie rod seal boot. If the seal boot is

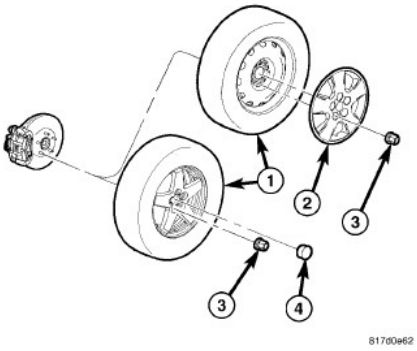
damaged, replace the outer tie rod end.

24. On each side of the gear, install the outer tie rod end (6) into the hole in the knuckle (2) arm. Start a NEW tie rod mounting nut (3) onto the stud. While holding the tie rod end stud with a wrench, tighten the nut with a wrench or crowfoot wrench. Tighten the nut to 85 N·m (63 ft. lbs.).

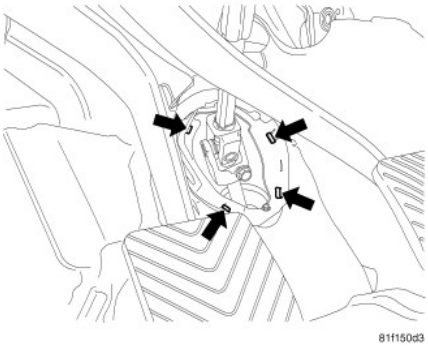


25. On each side of the vehicle, install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten the wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

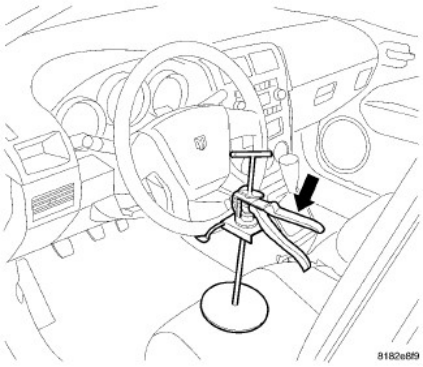
26. Lower the vehicle.



27. Lift the dash seal into position and engage the retaining clips securing the dash seal to the dash panel.



28. Remove the steering wheel holder using care not to rotate the steering wheel.



29. Verify the front wheels of vehicle are in the STRAIGHT-AHEAD position.

30. Center the intermediate shaft coupling (1) over the steering gear pinion shaft (3), then slide the intermediate shaft onto the steering gear pinion shaft.

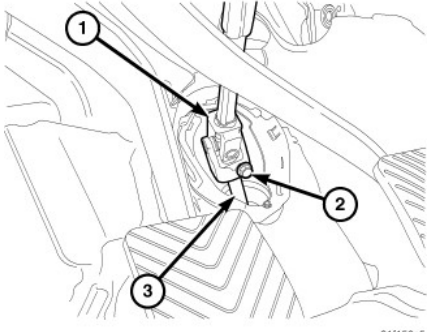
31. Install the intermediate shaft coupling bolt (2). Tighten the bolt to 42 N·m (31 ft. lbs.).

32. Position the sound deadening insulation and floor carpet back into place.

33. Fill and bleed the power steering system. (Refer to 19 - Steering - Standard Procedure)

34. Check for fluid leaks.

35. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)



2014 Dodge JC - DODGE JOURNEY

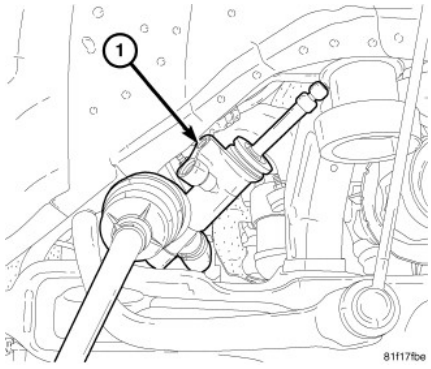
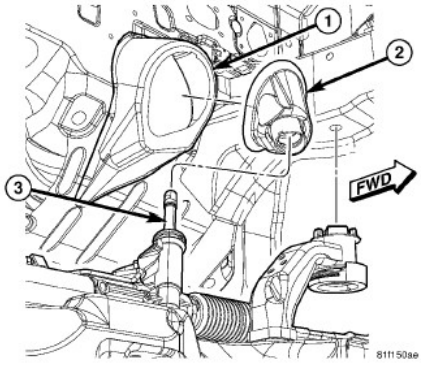
RIGHT-HAND DRIVE

Labor Operations: Click to display a list of Labor Operations associated with this procedure

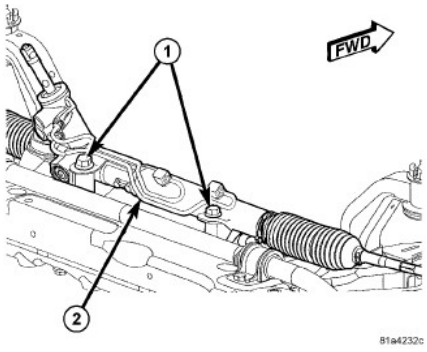
1. If necessary, install the outer tie rods onto the inner tie rod threads. As the outer tie rods are installed, count out same number of rotations as were counted on tie rod removal. This will get the toe setting somewhat close to specification before the vehicle is aligned at the end of this procedure. Snug the tie rod jam nuts on both ends of gear. Tighten the tie rod jam nuts to specification while performing the wheel alignment at the end of this procedure.
2. Tip the steering gear input shaft forward as needed, then slide the steering gear across the crossmember and out through right wheel opening.
3. Carefully install the steering gear (1) through the right wheel opening using the reverse of how it was removed. Slide it under the heat shield and move it across the crossmember until centered.



4. Tip the steering gear pinion shaft (3) straight up and install the dash seal (2) matching it to the contour of the steering gear housing.

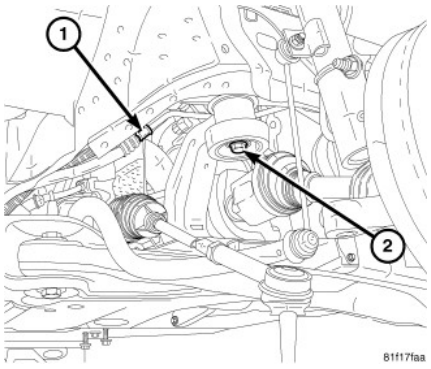


5. Place the steering gear in mounted position and install the two bolts (1) securing the steering gear (2) to the crossmember. Tighten the gear mounting bolts to 100 N·m (74 ft. lbs.).

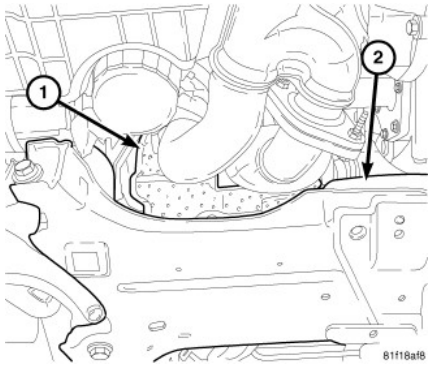


6. Install the right front crossmember mounting bolt (2). Tighten the mounting bolt to 135 N·m (100 ft. lbs.).

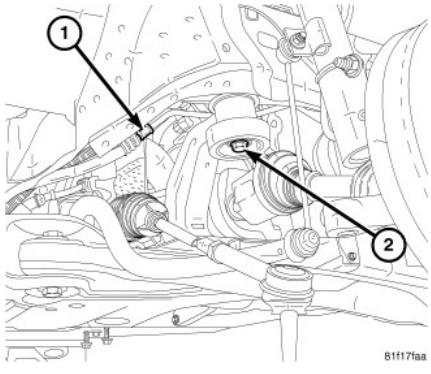
7. Center the power steering gear rack in its travel as necessary.



8. Install the heat shield over the steering gear. Install the mounting screws and push pins. Tighten the screws to 6 N·m (53 in. lbs.).

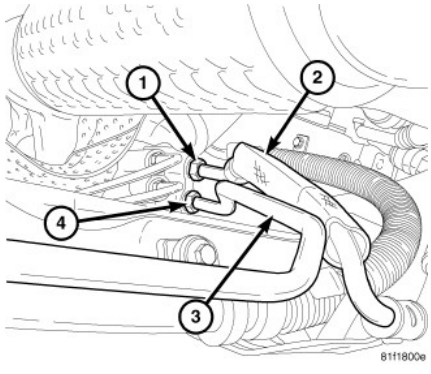


9. Position the power steering hose routing clamp on the right frame rail. Install and tighten the screw to 8 N·m (71 in. lbs.).

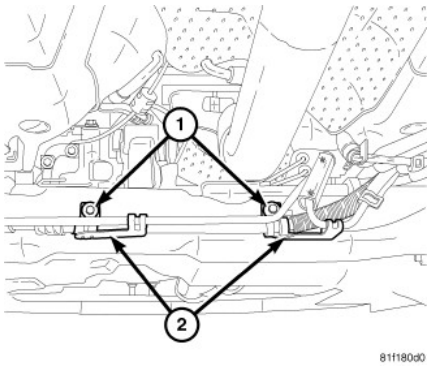


10. Install the pressure hose (3) tube at the gear. Tighten the tube nut (4) to 32 N·m (24 ft. lbs.).

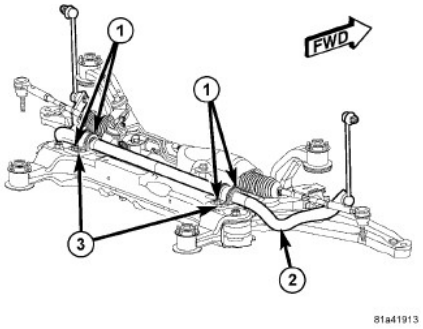
11. Install the return hose (2) tube at the gear. Tighten the tube nut (1) to 32 N·m (24 ft. lbs.).



12. Position the power steering hose routing clamps (2) on the rear of the crossmember. Install and tighten the screws (1) to 8 N·m (71 in. lbs.).



13. Install the screws (1) securing the stabilizer bushing retainers (3) to the crossmember. Tighten all four stabilizer bar cushion retainer screws to 60 N·m (44 ft. lbs.).

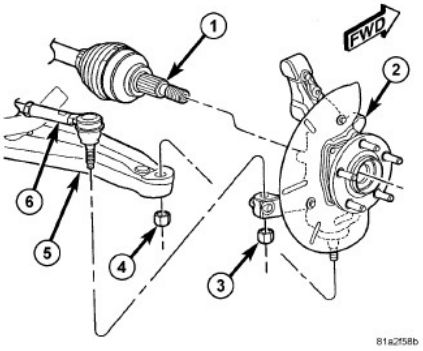


14. Install the rear engine mount. (Refer to 09 - Engine/Engine Mounting/INSULATOR, Engine Mount - Installation)

15. If equipped, install the engine belly pan.

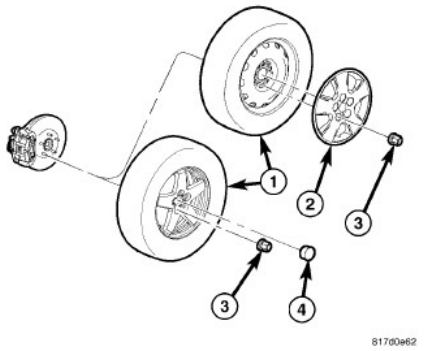
NOTE: Prior to attaching the outer tie rod end to the knuckle, inspect the tie rod seal boot. If the seal boot is damaged, replace the outer tie rod end.

16. On each side of the gear, install the outer tie rod end (6) into the hole in the knuckle (2) arm. Start a NEW tie rod mounting nut (3) onto the stud. While holding the tie rod end stud with a wrench, tighten the nut with a wrench or crowfoot wrench. Tighten the nut to 85 N·m (63 ft. lbs.).

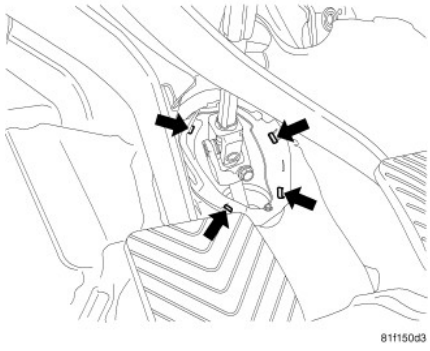


17. On each side of the vehicle, install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten the wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

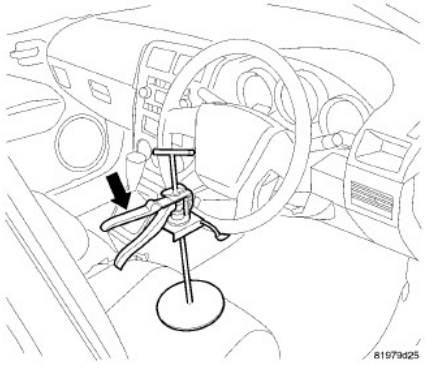
18. Lower the vehicle.



19. Lift the dash seal into position and engage the retaining clips securing the dash seal to the dash panel.



20. Remove the steering wheel holder.



21. Verify the front wheels of vehicle are in the STRAIGHT-AHEAD position.

22. Center the intermediate shaft coupling (1) over the steering gear pinion shaft (3), then slide the intermediate shaft onto the steering gear pinion shaft.

23. Install the intermediate shaft coupling bolt (2). Tighten the bolt to 42 N·m (31 ft. lbs.).

24. Position the sound deadening insulation and floor carpet back into place.

25. Fill and bleed the power steering system. (Refer to 19 - Steering - Standard Procedure)

26. Check for fluid leaks.

27. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)

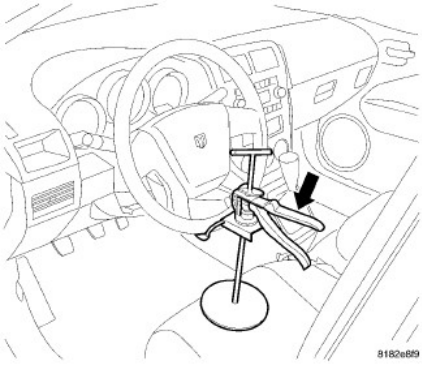
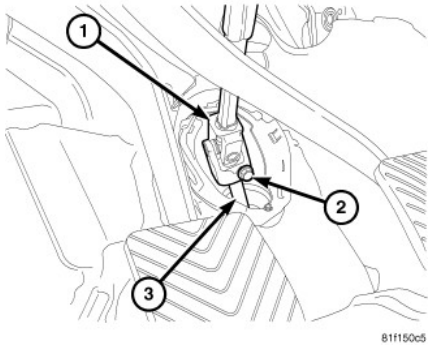
LEFT-HAND DRIVE - AWD

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

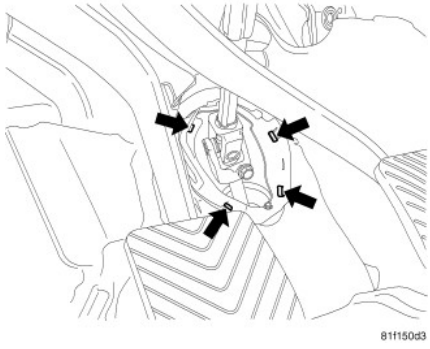
NOTE: Before proceeding, (Refer to 19 - Steering - Warning) .



1. Siphon out as much power steering fluid as possible from the reservoir.
2. Place the front wheels of vehicle (and steering wheel) in the STRAIGHT-AHEAD position. Using a steering wheel holder, lock the steering wheel in place to keep it from rotating. This keeps the clockspring in the proper orientation while the intermediate shaft is disconnected.

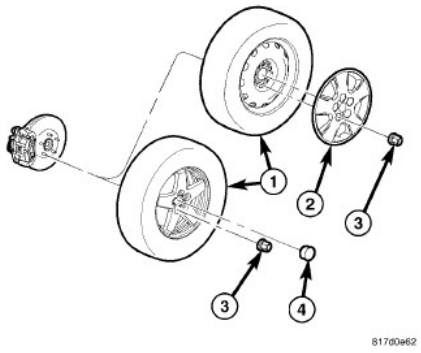


3. Reposition the floor carpeting and sound deadening insulation to access the intermediate shaft coupling (1) at the base of the column.
4. Remove the intermediate shaft coupling bolt (2).
5. Separate the intermediate shaft coupling (1) from the steering gear pinion shaft (3).

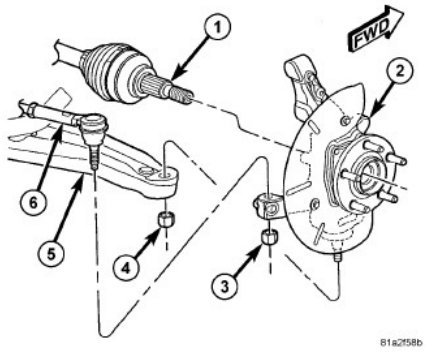


6. Release the clips securing the dash seal to the dash panel and push the seal away from the dash panel.
7. Raise and support the vehicle (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)

8. On each side of the vehicle, remove the wheel mounting nuts (3), then the tire and wheel assembly (1).

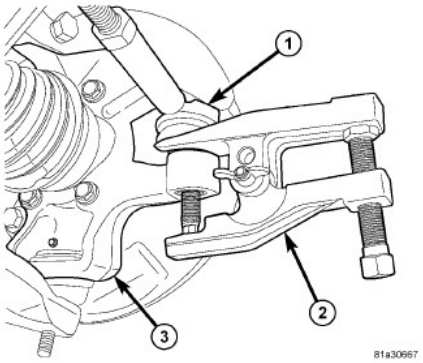


9. On each side of the gear, remove the nut (3) from the out tie rod end (6) at the knuckle (2).

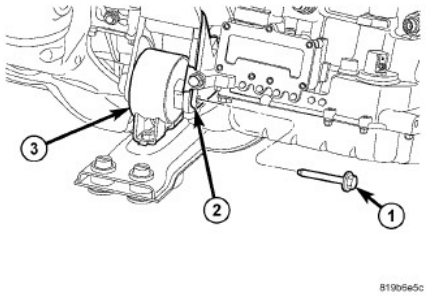


10. On each side of the gear, separate the outer tie rod end (1) from the knuckle (3) using Remover (2), Special Tool 9360 .

11. If equipped, remove the engine belly pan.



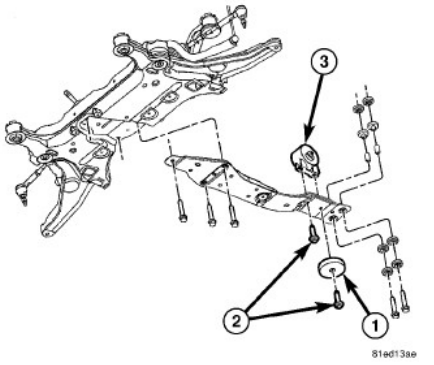
12. Remove the front engine mount through-bolt (1).



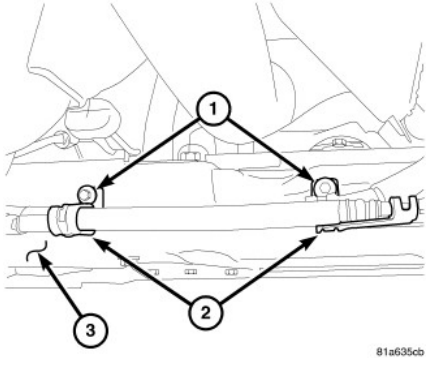
13. Remove the fore-aft crossmember forward mounting bolts at the radiator support.

14. Remove the fore-aft crossmember rearward mounting bolts at the crossmember.

15. Remove the fore-aft crossmember.



16. Remove the screws (1) securing the power steering hose routing clamps (2) to the rear of the crossmember.

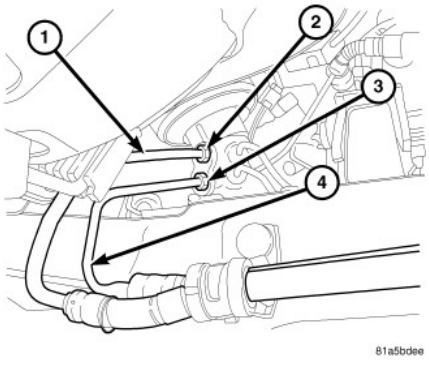


17. Unscrew the tube nut (2), then remove the return hose (1) at the steering gear.

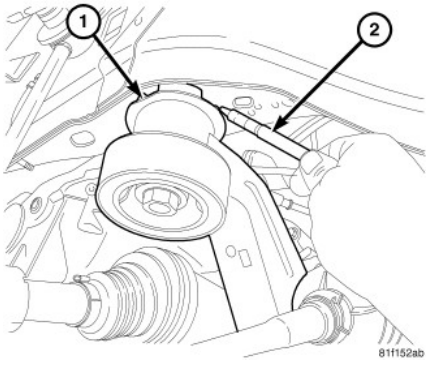
18. Unscrew the tube nut (3), then remove the pressure hose (4) at the steering gear.

NOTE:

Before lowering the front suspension crossmember, the location of the crossmember must be marked on the body of the vehicle. Do this so the crossmember can be relocated, upon reinstallation, against the body of vehicle in the same location as before removal. If the front suspension crossmember is not reinstalled in exactly the same location as before removal, the preset front wheel alignment settings (caster and camber) may be lost.



19. Using a crayon or marker (2) that will not break the paint surface, mark the location of the front crossmember (1) on the body near each mounting bolt. **Do not use any type of sharp instrument that will damage the underbody of the vehicle.**

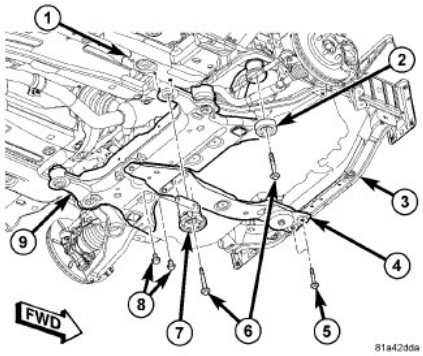


20. Support the crossmember (9) with a transmission jack.

21. Remove the four mounting bolts (6) securing the front crossmember (9) to the body.

22. Remove the mounting screws (8) securing the front crossmember reinforcement brackets (7) (one each side of vehicle) to the body (1). Remove the brackets.

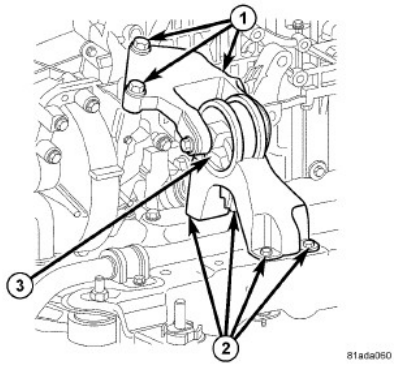
23. Using the jack, slowly lower the crossmember approximately 3 inches (76 mm) (as measured at the rear crossmember mounts). **Do not lower the crossmember more than necessary as damage may occur.**



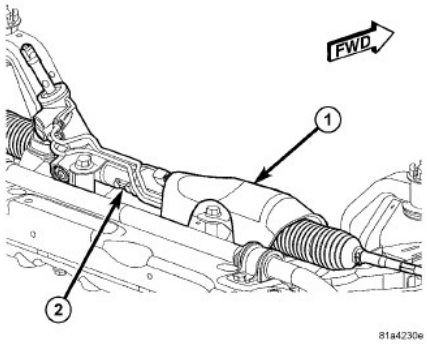
24. Remove the rear mount through bolt.

25. Remove the four bolts (2) from the rear isolator (3) to crossmember.

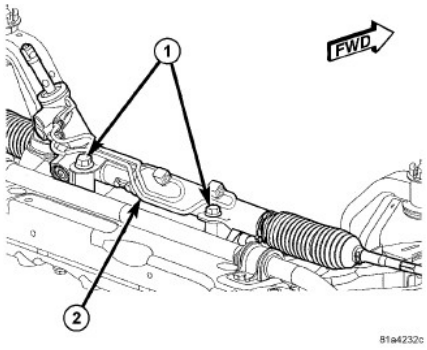
26. Remove the rear isolator (3) from the vehicle.



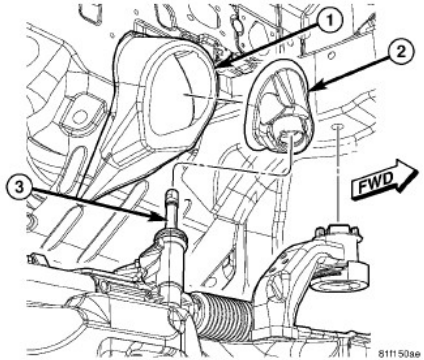
27. Remove the screws and push-pins securing the heat shield (1) over the right side of the steering gear (2). Remove the shield.



28. Remove the two bolts (1) securing the steering gear (2) to the crossmember.



29. Tip the steering gear pinion shaft (3) straight up and remove the dash seal (2) from the steering gear.



30. Slide the steering gear across the crossmember and out through left wheel opening.

31. If necessary, remove outer tie rods from inner tie rod threads. Count how many rotations it takes to remove each outer tie rod for installation reference.

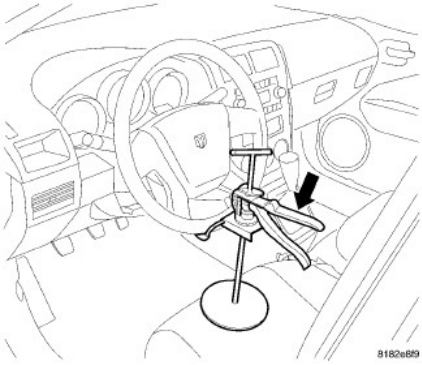
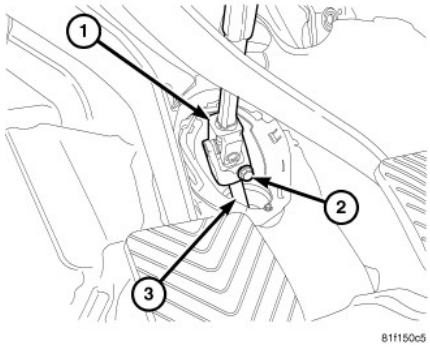
LEFT-HAND DRIVE - FWD

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

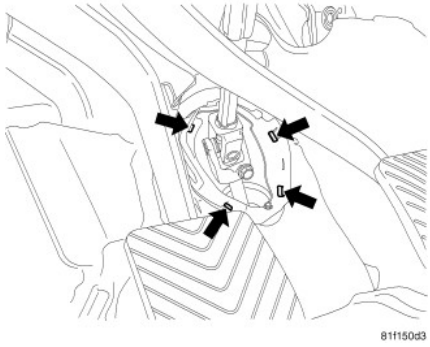
NOTE: Before proceeding, (Refer to 19 - Steering - Warning) .



1. Siphon out as much power steering fluid as possible from the reservoir.
2. Place the front wheels of vehicle (and steering wheel) in the STRAIGHT-AHEAD position. Using a steering wheel holder, lock the steering wheel in place to keep it from rotating. This keeps the clockspring in the proper orientation while the intermediate shaft is disconnected.

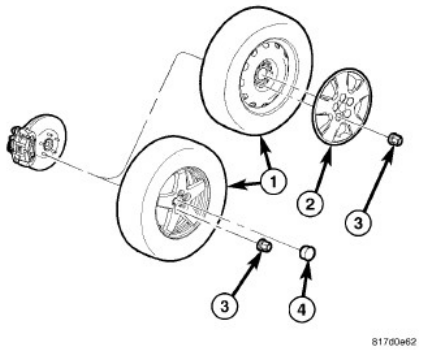


3. Reposition the floor carpeting and sound deadening insulation to access the intermediate shaft coupling (1) at the base of the column.
4. Remove the intermediate shaft coupling bolt (2).
5. Separate the intermediate shaft coupling (1) from the steering gear pinion shaft (3).

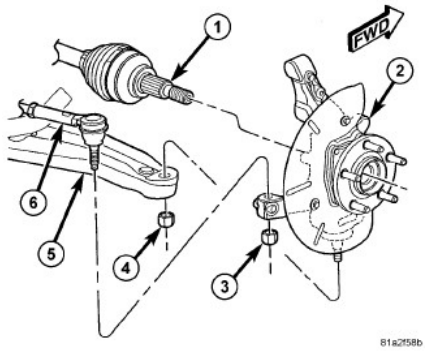


6. Release the clips securing the dash seal to the dash panel and push the seal away from the dash panel.
7. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)

8. On each side of the vehicle, remove the wheel mounting nuts (3), then the tire and wheel assembly (1).

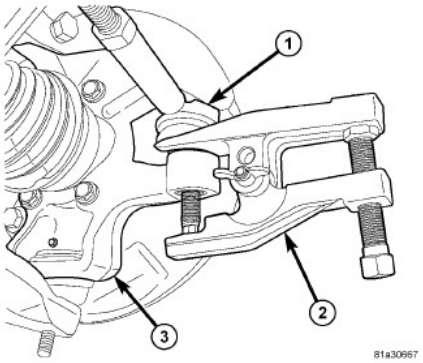


9. On each side of the gear, remove the nut (3) from the out tie rod end (6) at the knuckle (2).

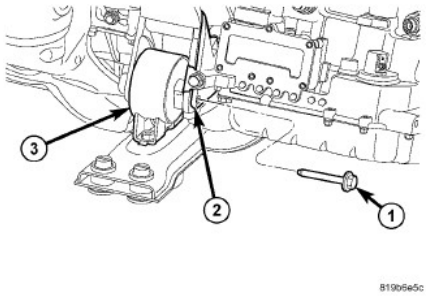


10. On each side of the gear, separate the outer tie rod end (1) from the knuckle (3) using Remover (2), Special Tool 9360 .

11. If equipped, remove the engine belly pan.



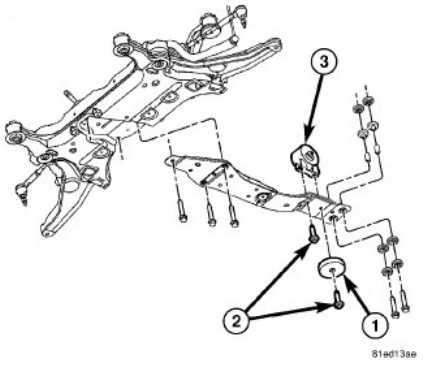
12. Remove the front engine mount through-bolt (1).



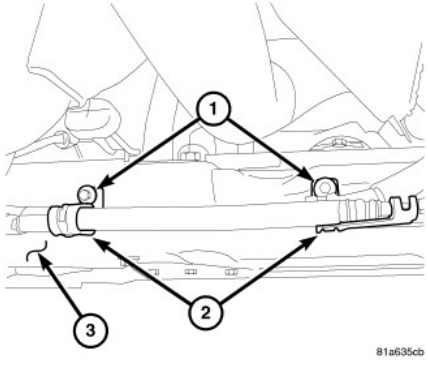
13. Remove the fore-aft crossmember forward mounting bolts at the radiator support.

14. Remove the fore-aft crossmember rearward mounting bolts at the crossmember.

15. Remove the fore-aft crossmember.

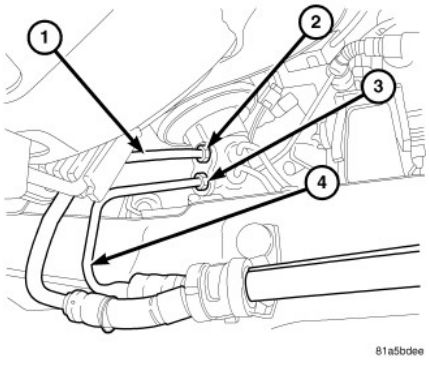


16. Remove the screws (1) securing the power steering hose routing clamps (2) to the rear of the crossmember.



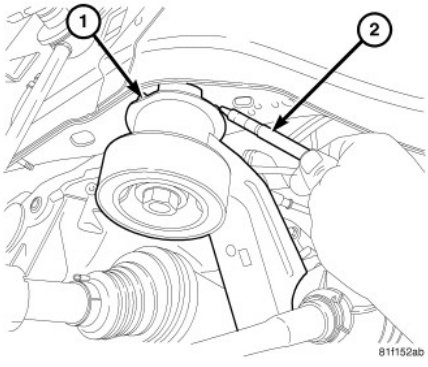
17. Unscrew the tube nut (2), then remove the return hose (1) at the steering gear.

18. Unscrew the tube nut (3), then remove the pressure hose (4) at the steering gear.



NOTE:

Before lowering the front suspension crossmember, the location of the crossmember must be marked on the body of the vehicle. Do this so the crossmember can be relocated, upon reinstallation, against the body of vehicle in the same location as before removal. If the front suspension crossmember is not reinstalled in exactly the same location as before removal, the preset front wheel alignment settings (caster and camber) may be lost.



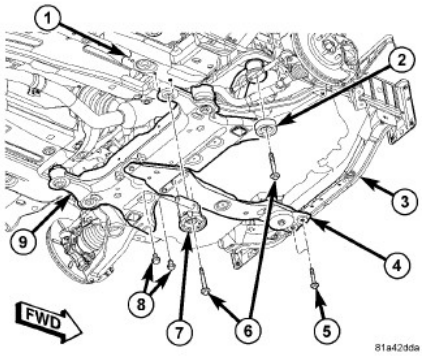
19. Using a crayon or marker (2) that will not break the paint surface, mark the location of the front crossmember (1) on the body near each mounting bolt. **Do not use any type of sharp instrument that will damage the underbody of the vehicle.**

20. Support the crossmember (9) with a transmission jack.

21. Remove the four mounting bolts (6) securing the front crossmember (9) to the body.

22. Remove the mounting screws (8) securing the front crossmember reinforcement brackets (7) (one each side of vehicle) to the body (1). Remove the brackets.

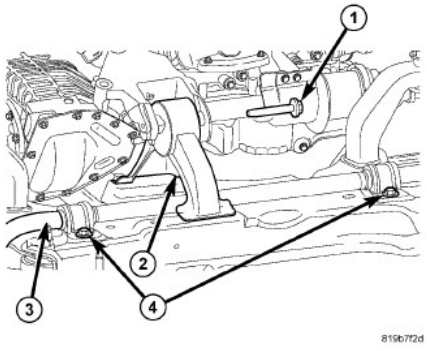
23. Using the jack, slowly lower the crossmember approximately 3 inches (76 mm) (as measured at the rear crossmember mounts). **Do not lower the crossmember more than necessary as the fore/aft crossmember is still attached to the radiator support and damage may occur.**



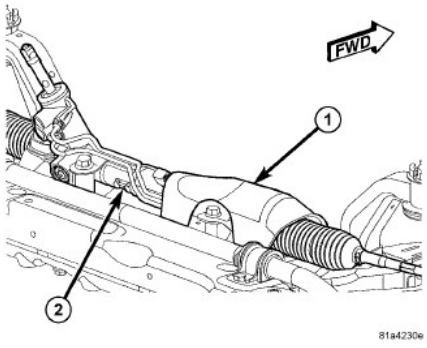
24. Remove the rear engine mount through-bolt (1).

25. Remove the four bolts that hold the rear isolator to the cross member.

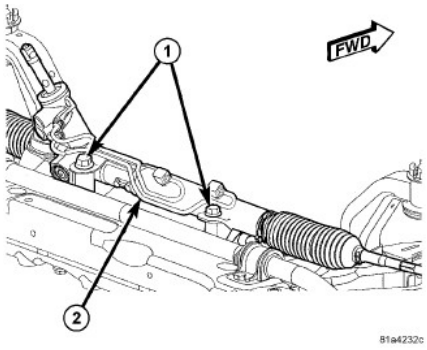
26. Remove the rear isolator (2) from the vehicle.



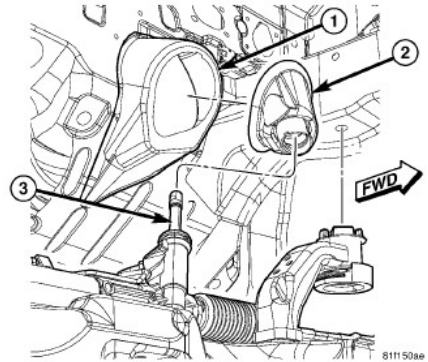
27. Remove the screws and push-pins securing the heat shield (1) over the right side of the steering gear (2). Remove the shield.



28. Remove the two bolts (1) securing the steering gear (2) to the crossmember.



29. Tip the steering gear pinion shaft (3) straight up and remove the dash seal (2) from the steering gear.



30. Slide the steering gear across the crossmember and out through left wheel opening.

31. If necessary, remove outer tie rods from inner tie rod threads. Count how many rotations it takes to remove each outer tie rod for installation reference.

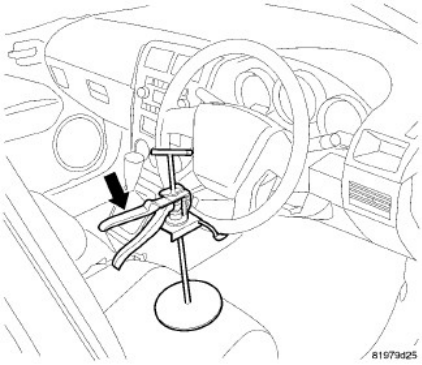
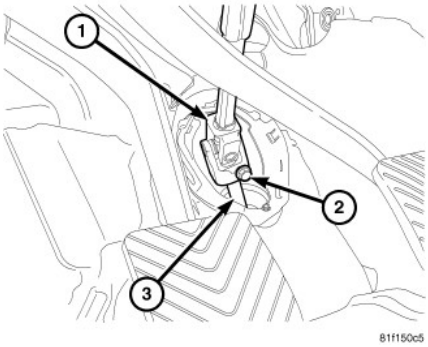
RIGHT HAND DRIVE

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

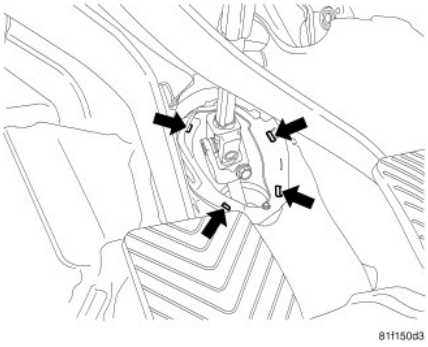
NOTE: Before proceeding, (Refer to 19 - Steering - Warning) .



1. Siphon out as much power steering fluid as possible from the reservoir.
2. Place the front wheels of the vehicle (and steering wheel) in the STRAIGHT-AHEAD position. Using a steering wheel holder, lock the steering wheel in place to keep it from rotating. This keeps the clockspring in the proper orientation while the intermediate shaft is disconnected.

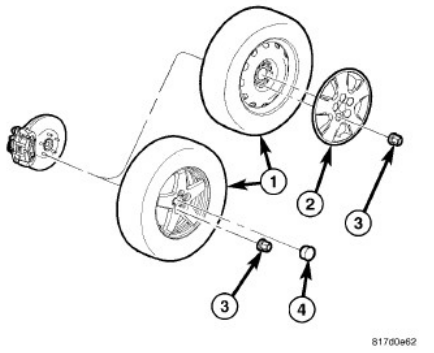


3. Reposition the floor carpeting and sound deadening insulation to access the intermediate shaft coupling (1) at the base of the column.
4. Remove the intermediate shaft coupling bolt (2).
5. Separate the intermediate shaft coupling (1) from the steering gear pinion shaft (3).

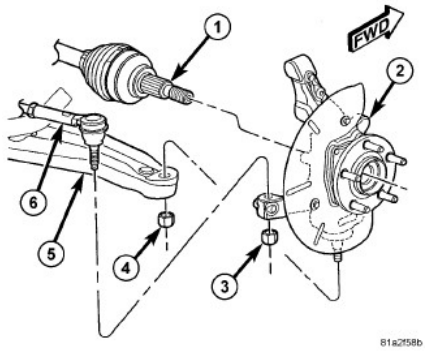


6. Release the clips securing the dash seal to the dash panel and push the seal away from the dash panel.
7. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)

8. On each side of the vehicle, remove the wheel mounting nuts (3), then the tire and wheel assembly (1).



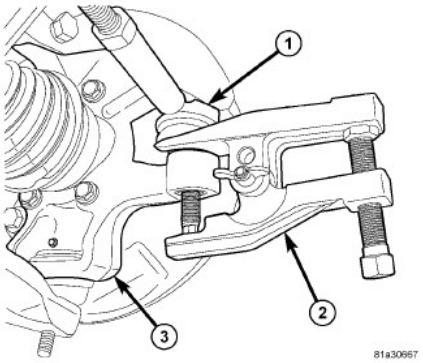
9. On each side of the gear, remove the nut (3) from the out tie rod end (6) at the knuckle (2).



10. On each side of the gear, separate the outer tie rod end (1) from the knuckle (3) using Remover (2), Special Tool 9360 .

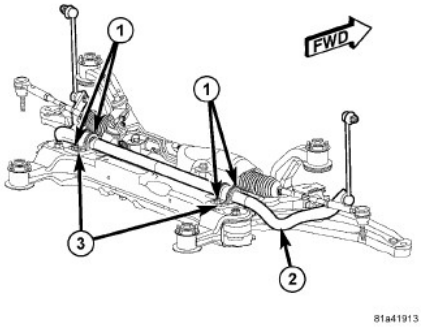
11. If equipped, remove the engine belly pan.

12. Remove the rear engine mount. (Refer to 09 - Engine/Engine Mounting/INSULATOR, Engine Mount - Removal)

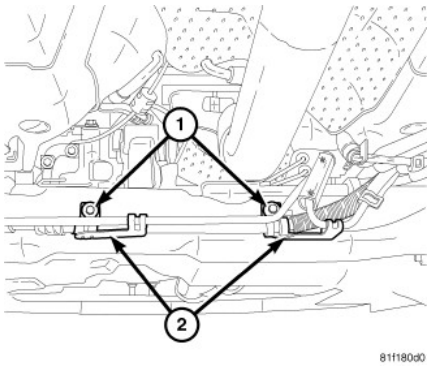


13. Remove the screws (1) securing the stabilizer bushing retainers (3) to the crossmember.

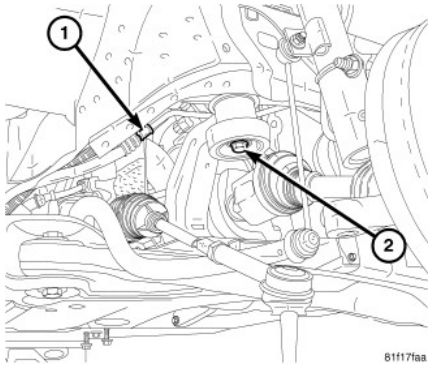
14. Move the stabilizer bar rearward on the crossmember.



15. Remove the screws (1) securing the power steering hose routing clamps (2) to the rear of the crossmember.

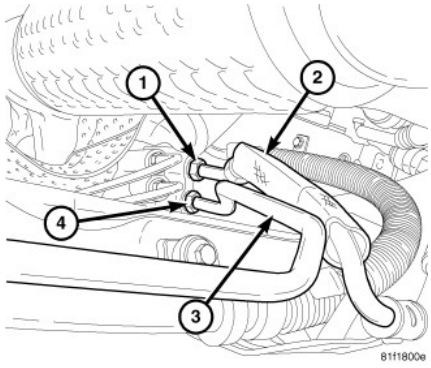


16. Remove the screw securing the power steering hose routing clamp (1) to right frame rail.

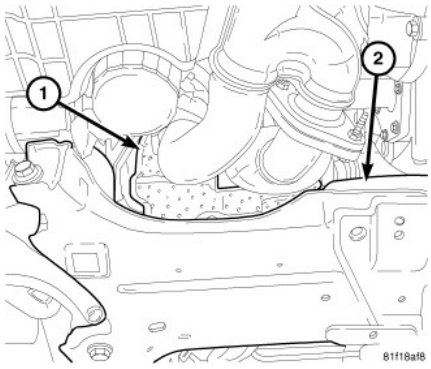


17. Unscrew the tube nut (1), then remove the return hose (2) from the steering gear. Move the hose away from the gear.

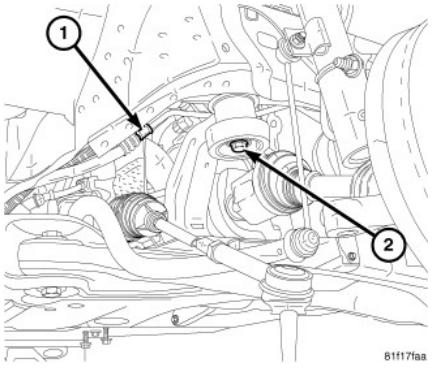
18. Unscrew the tube nut (4), then remove the pressure hose (3) from the steering gear. Move the hose away from the gear.



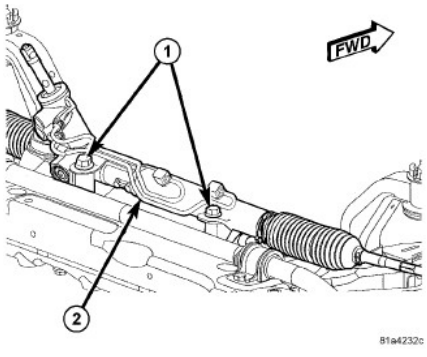
19. Remove the screws and push-pins securing the heat shield (1) over the steering gear.



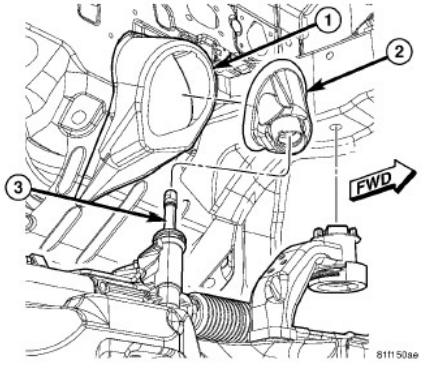
20. Remove the right front crossmember mounting bolt (2) allowing that corner of the front crossmember to sag downward.



21. Remove the two bolts (1) securing the steering gear (2) to the crossmember.



22. Tip the steering gear pinion shaft (3) straight up and remove the dash seal (2) from the steering gear. Move the seal upward, away from the gear and support there.



23. Tip the steering gear input shaft forward as needed, then slide the steering gear across the crossmember and out through right wheel opening.

24. If necessary, remove outer tie rods from inner tie rod threads. Count how many rotations it takes to remove each outer tie rod for installation reference.

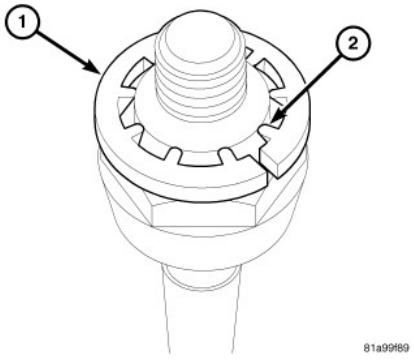
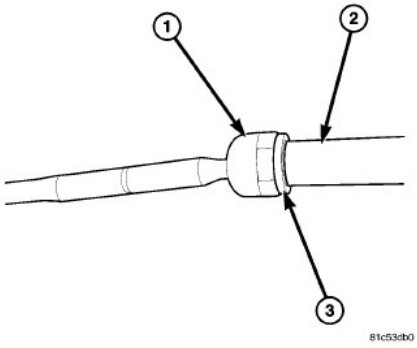
INNER TIE ROD

Labor Operations: Click to display a list of Labor Operations associated with this procedure

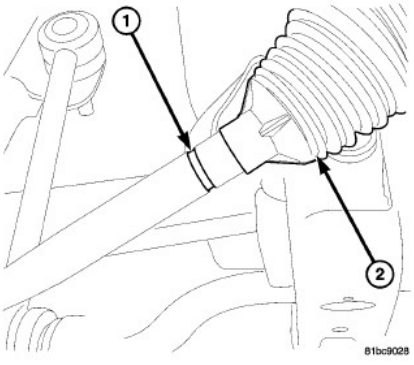
CAUTION: **When installing the travel restrictor, be sure to use the same color and thickness travel restrictor as was removed. This action is necessary to properly set gear travel for the steering gear being serviced. Travel restrictor thickness can vary side-to-side on the steering gear.**



1. Install the travel restrictor (1), flat side of teeth (2) facing out, on the inboard end of the inner tie rod ball joint.
2. Apply Mopar® Lock AND Seal Adhesive or equivalent medium thread locker adhesive to the inboard end threads of the inner tie rod.

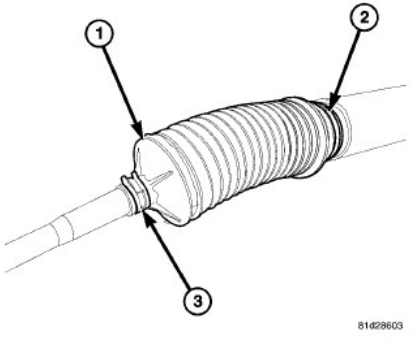


3. Install the inner tie rod (1) onto the gear (2) using an appropriate inner tie rod installation tool or crows foot wrench on the hex. Tighten the inner tie rod to 78 N·m, (58 ft. lbs.).
4. Loosely place a NEW clamp over the large end of the NEW bellows.
5. Slide the NEW bellows with clamp over the end of the inner tie rod and onto the gear body.

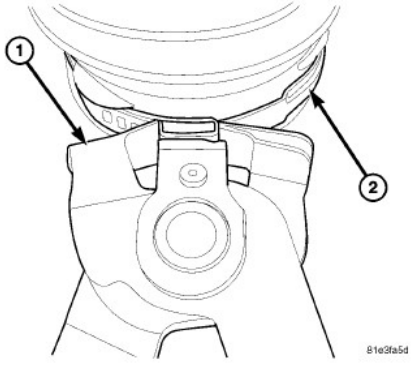


6. Push the small end of the bellows (2) past the groove (1) machined into the inner tie rod.
7. Apply a small amount of Mopar® Lubriplate or equivalent uniformly to the groove (1) in the inner tie rod shaft. This allows for toe adjustment without twisting the bellows.
8. Pull the small end of the bellows outward until the ridge inside the bellows engages the groove.

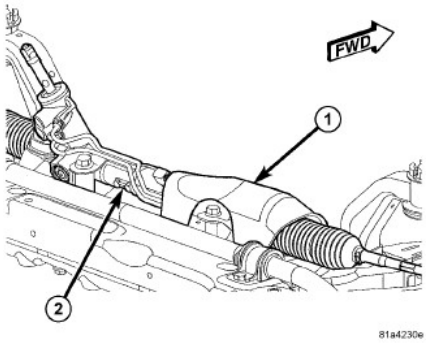
9. Install a NEW clamp (3) over the small end of the bellows (1).



10. Using crimping pliers (1), crimp the large clamp (2) securing the bellows to the gear body.



11. If servicing the right inner tie rod, position the heat shield (1) over the steering gear (2). Install mounting screws and push-pins. Tighten the screws to 6 N·m (53 in. lbs.).



12. Thread the tie rod jam nut onto the inner tie rod far enough to install the outer tie rod.

13. Install the outer tie rod. (Refer to 19 - Steering/Gear/TIE ROD, Steering - Installation)

2014 Dodge JC - DODGE JOURNEY

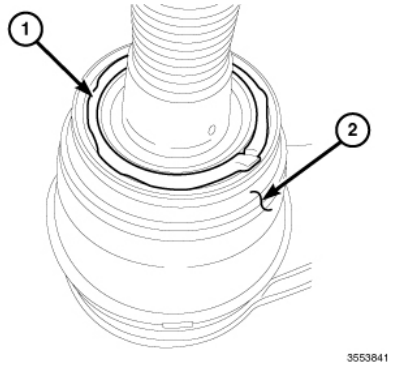
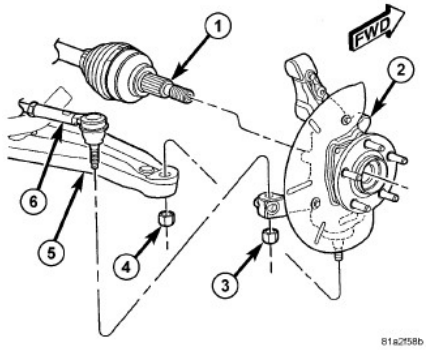
OUTER TIE ROD END

Labor Operations: Click to display a list of Labor Operations associated with this procedure

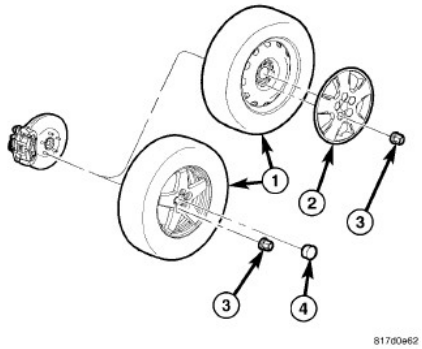
NOTE: If a new tie rod end is to be installed, make sure the boot (2) is properly lubricated.



1. Clean all old grease and debris from the boot (2) with a clean cloth.
2. Apply outer tie rod grease P/N 68088623AA (1) to the tie rod end boot (2).



3. If it is not already installed, install the jam nut on the inner tie rod threads. Thread the jam nut down the inner tie rod far enough to allow for outer tie rod installation.
4. Thread the outer tie rod onto the inner tie rod approximately the same amount of revolutions as the original was installed. Do not tighten the jam nut at this time.
5. Install the outer tie rod end (6) into the hole in the knuckle (2) arm. Start a NEW tie rod mounting nut (3) onto the stud. While holding the tie rod end stud with a wrench, tighten the nut with a wrench or crowfoot wrench. Tighten the nut to 85 N·m (63 ft. lbs.).

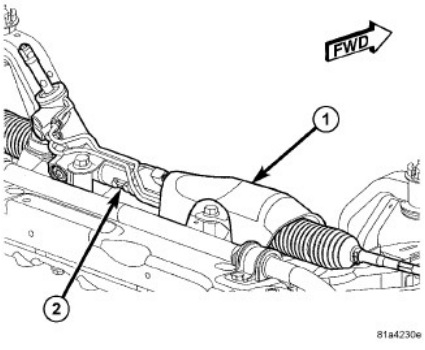


6. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).
7. Lower the vehicle.
8. Adjust the front wheel toe setting. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure) .
9. Tighten the tie rod jam nut to 75 N·m (55 ft. lbs.) once wheel toe is set.

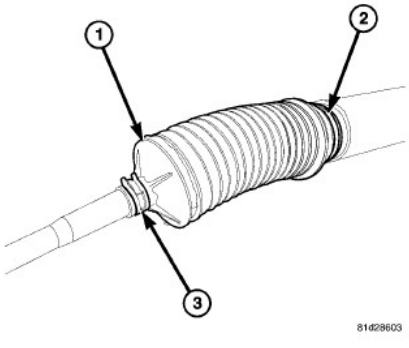
INNER TIE ROD

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Remove the outer tie rod. (Refer to 19 - Steering/Gear/TIE ROD, Steering - Removal)
2. Remove the tie rod jam nut from the inner tie rod.
3. If servicing the right inner tie rod, remove the screws and push-pins securing the heat shield (1) over the right side of the steering gear (2). Remove the heat shield from over the bellows.



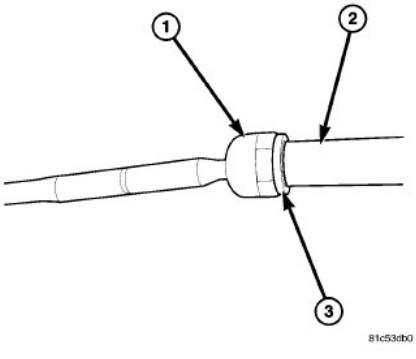
4. Remove the clamp (3) securing the bellows (1) to the inner tie rod.
5. Remove the clamp (2) securing the bellows (1) to the steering gear body.
6. Remove the bellows.



7. Remove the travel restrictor (3) from the inner tie rod (1).
8. Install an appropriate inner tie rod removal tool on the inner tie rod (1) hex.

CAUTION: **If the inner tie rod cannot be removed using the specified tools, do not use a hammer or heat to loosen. Damage to the steering gear will occur. Replace the entire steering gear.**

9. Unthread and remove the inner tie rod (1) from the steering gear (2).



2014 Dodge JC - DODGE JOURNEY

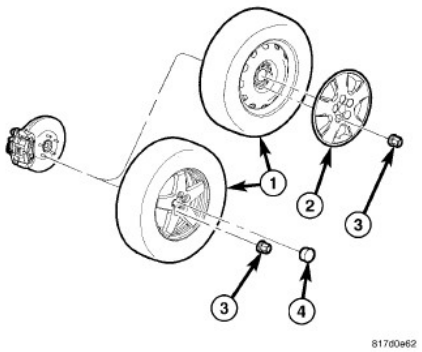
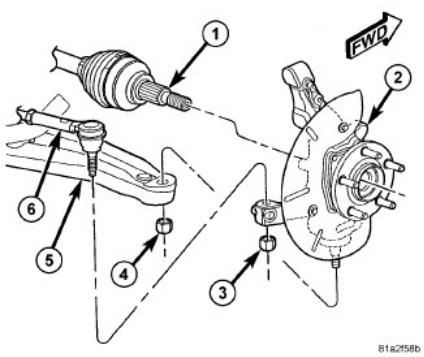
OUTER TIE ROD END

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)
2. Remove the wheel mounting nuts (3) , then the tire and wheel assembly (1).



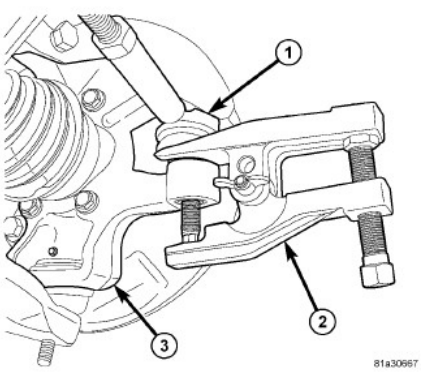
3. Loosen the tie rod jam nut.
4. Remove the nut (3) attaching the outer tie rod end (6) to the knuckle (2). To do this, hold the tie rod end stud with a wrench while loosening and removing the nut with a standard wrench or crowfoot wrench.



5. Separate the outer tie rod end (1) from the knuckle (3) using Remover (2), Special Tool 9360 . Remove the outer tie rod from the knuckle.

NOTE: When unscrewing the outer tie rod from inner, count the number of revolutions to take it off. This action will aid in installation, getting the toe close to where it needs to be when setting the wheel alignment.

6. Remove the outer tie rod from the inner tie rod.



2014 Dodge JC - DODGE JOURNEY

OPERATION

Turning of the steering wheel is converted into linear (side-to-side) travel through the meshing of the helical pinion teeth with the rack teeth within the steering gear. The lateral travel pushes and pulls the tie rods to change the direction of the vehicle's front wheels.

Power assist steering is provided by a belt driven rotary type pump. It directs fluid through power steering fluid hoses to the power steering gear where it is used to assist the driver's turning effort.

Manual steering control of the vehicle can be maintained if power steering assist is lost. However, under this condition, steering effort is significantly increased.

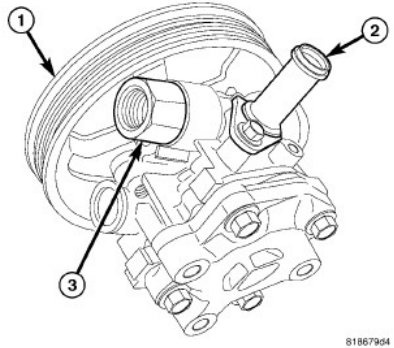
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Hydraulic pressure for operation of the power steering gear is provided by a droop-flow type power steering pump.

The power steering pump is belt driven. The pulley (1) cannot be serviced separately on four-cylinder engine mounted pumps.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The recommended fluid for the power steering system is Mopar® Power Steering fluid + 4 or Mopar® ATF+4 Automatic Transmission Fluid. Both fluids have the same material standard specifications (MS-9602).

Mopar® ATF+4 (and Mopar® Power Steering fluid + 4), when new, is red in color. ATF+4 is dyed red so it can be identified from other fluids used in the vehicle such as engine oil or antifreeze. The red color is not permanent and is not an indicator of fluid condition. As the vehicle is driven, ATF+4 will begin to look darker in color and may eventually become brown. **THIS IS NORMAL.** ATF+4 also has a unique odor that may change with age. Consequently, odor and color cannot be used to indicate the fluid condition or the need for a fluid change.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

STANDARD PROCEDURE - POWER STEERING FLUID LEVEL CHECKING

WARNING: **Fluid level should be checked with the engine OFF to prevent personal injury from moving parts and to assure an accurate fluid level reading.**

CAUTION: **Mopar® Power Steering Fluid + 4 or Mopar® ATF+4 Automatic Transmission Fluid is to be used in the power steering system. Both Fluids have the same material standard specifications (MS-9602). No other power steering or automatic transmission fluid is to be used in the system. Damage may result to the power steering pump and system if another fluid is used. Do not overfill the system.**

NOTE: Although not required at specific intervals, the fluid level may be checked periodically. Check the fluid level anytime there is a system noise or fluid leak suspected.

The power steering fluid level can be viewed through the side of the power steering fluid reservoir. Compare the fluid level to the markings on the side of the reservoir. When the fluid is at normal ambient temperature, approximately 21°C to 27°C (70°F to 80°F), the fluid level should read between the MAX. and MIN. markings. When the fluid is hot, fluid level is allowed to read up to the MAX. line.

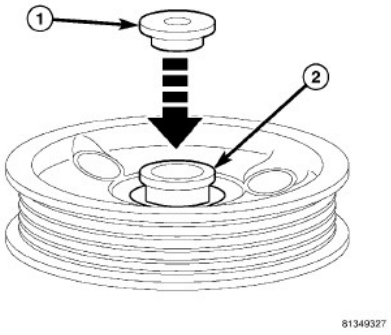
INSTALLATION

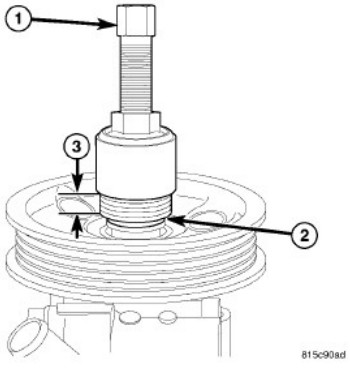
Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

CAUTION: **Do not hammer on power steering pump pulley (2) or pump shaft to install pulley. This action will damage pulley and power steering pump.**



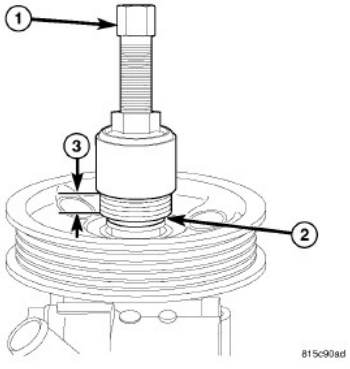
1. Place power steering pump pulley (2) squarely on end of power steering pump shaft.
2. Place Installation Spacer 6936 (1), on top of pump pulley (2).

NOTE: Later build pumps feature a shaft with internal threads that are not as deep as earlier production, thus requiring a stack of washers, approximately 13 mm (0.5 in.) thickness (3), placed over Spacer 6936 (2), before mounting Installer C-4063C (1) on the pump. To know if a replacement pump requires the stack of washers, measure the depth of the shaft hole. A later build pump will have a depth of 20 mm (0.78 in.) while an earlier build pump will have a depth of 32 mm (1.25 in.).



3. As necessary (see above note), place a stack of washers approximately 13 mm (0.5 in.) thickness (3) over Spacer 6936 (2).

NOTE: It is important to use Forcing Screw C-4063-2 when performing this procedure.



4. Thread Installer C-4063C (1), completely into internal threads of power steering pump shaft, then rotate Installer Nut down against washers (as necessary) and Spacer (2) on pump pulley.
5. Ensuring that the tools and pulley remain aligned with pump shaft, tighten Installer Nut, forcing pulley onto power steering pump shaft until Spacer (2) comes in contact with end of pump shaft. **When Spacer (2) is against shaft of power steering pump, Installer (1) Nut will no longer rotate.**
6. Install power steering pump on engine. (Refer to 19 - Steering/Pump - Installation) .

2014 Dodge JC - DODGE JOURNEY

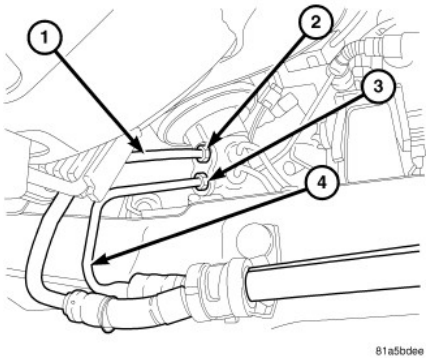
CAUTION: **Power steering fluid hoses must remain away from the exhaust system, driveshafts, vehicle components and any unfriendly surface that can possibly damage the hoses.**

1. Install the pressure hose tube (4) at the gear. Tighten the tube nut (3) to 32 N·m (24 ft. lbs.).



2. Position the power steering hose routing clamps (2) on the crossmember. Install and tighten the screws to 8 N·m (71 in. lbs.).

3. Using a lint free towel, wipe clean the open power steering pressure hose end and the power steering pump port. Replace any used O-rings with new. Lubricate the O-ring with clean power steering fluid.
4. Install the pressure hose (2) at the pump pressure port. Tighten the tube nut to 32 N·m (24 ft. lbs.).
5. Lower the vehicle.
6. Fill and bleed the power steering system (Refer to 19 - Steering - Standard Procedure) .
7. Check for leaks.

STANDARD PROCEDURE - POWER STEERING SYSTEM BLEEDING

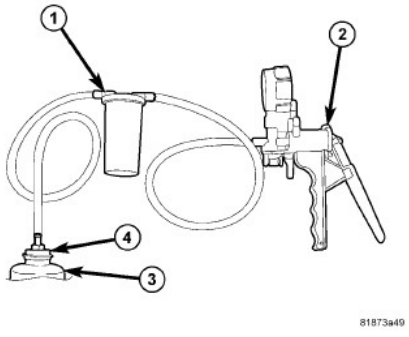
Special Tools: Click to display a list of tools used in this procedure

WARNING: **The fluid level should be checked with engine off to prevent injury from moving components.**

CAUTION: **Mopar® Power Steering Fluid + 4 or Mopar® ATF+4 Automatic Transmission Fluid is to be used in the power steering system. Both Fluids have the same material standard specifications (MS-9602). No other power steering or automatic transmission fluid is to be used in the system. Damage may result to the power steering pump and system if another fluid is used. Do not overfill the system.**

CAUTION: **If the air is not purged from the power steering system correctly, pump failure could result.**

NOTE: Be sure the vacuum tool used in the following procedure is clean and free of any fluids.



1. Check the fluid level. As measured on the side of the reservoir, the level should indicate between MAX and MIN when the fluid is at normal ambient temperature. Adjust the fluid level as necessary. (Refer to 19 - Steering/Pump/FLUID - Standard Procedure)
2. Tightly insert Power Steering Cap Adapter (4), Special Tool 9688A , into the mouth of the reservoir (3).

CAUTION: **Failure to use a vacuum pump reservoir (1) may allow power steering fluid to be sucked into the hand vacuum pump.**

3. Attach Hand Vacuum Pump (2), Special Tool C-4207-A or equivalent, with reservoir (1) attached, to the Power Steering Cap Adapter (4).

CAUTION: **Do not run the engine while vacuum is applied to the power steering system. Damage to the power steering pump can occur.**

NOTE: When performing the following step make sure the vacuum level is maintained during the entire time period.

4. Using Hand Vacuum Pump (2), apply 68-85 kPa (20-25 in. Hg) of vacuum to the system for a minimum of three minutes.
5. Slowly release the vacuum and remove the special tools.
6. Adjust the fluid level as necessary. Refer to **Step #1**.
7. Repeat **Step #1** through **Step #6** until the fluid no longer drops when vacuum is applied.

8. Start the engine and cycle the steering wheel lock-to-lock three times.

NOTE: Do not hold the steering wheel at the stops.

9. Stop the engine and check for leaks at all connections.

10. Check for any signs of air in the reservoir and check the fluid level. If air is present, repeat the procedure as necessary.

WARNING

WARNING: **Power steering fluid, engine parts and exhaust system may be extremely hot if engine has been running. Do not start engine with any loose or disconnected hoses. Do not allow hoses to touch hot exhaust manifold or catalyst.**

WARNING: **Fluid level should be checked with the engine off to prevent personal injury from moving parts.**

CAUTION: **When the system is open, cap all open ends of the hoses, power steering pump fittings or power steering gear ports to prevent entry of foreign material into the components.**

Fuel Delivery: | **Fuel:**

POWER STEERING FLUID

The recommended fluid for the power steering system is Mopar® Power Steering fluid + 4 or Mopar® ATF+4 Automatic Transmission Fluid. Both Fluids have the same material standard specifications (MS-9602).

Mopar® ATF+4 (and Mopar® Power Steering fluid + 4), when new, is red in color. ATF+4 is dyed red so it can be identified from other fluids used in the vehicle such as engine oil or antifreeze. The red color is not permanent and is not an indicator of fluid condition. As the vehicle is driven, ATF+4 will begin to look darker in color and may eventually become brown. **THIS IS NORMAL**. ATF+4 also has a unique odor that may change with age. Consequently, odor and color cannot be used to indicate the fluid condition or the need for a fluid change.

The power steering system is filled-for-life at the factory and requires no regular maintenance. Although not required at specific intervals, the fluid level may be checked periodically. Check the fluid level anytime there is a system noise or fluid leak suspected. (Refer to 19 - Steering/Pump/FLUID - Standard Procedure)

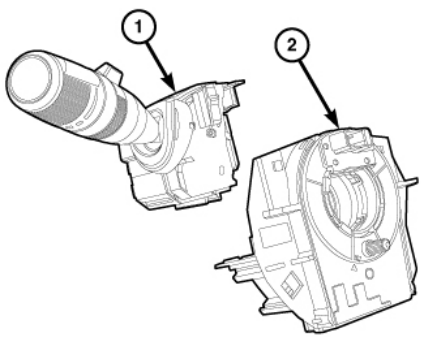
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

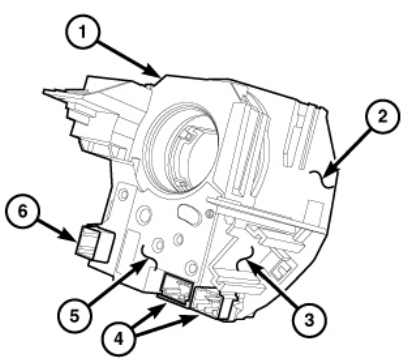
The steering angle sensor (SAS) is an integral part of the clockspring (2) mounted on the steering column (Refer to 10 - Restraints/CLOCKSPRING - Description) .

The SAS detects steering wheel direction, angular magnitude and rotational velocity and transmits this data over the high speed serial communication bus (CAN-C) for the Electronic Stability Control (ESC) system.



3605373

The SAS (5) includes an integral Local Interface Network (LIN) data bus master node and is also a gateway to the Controller Area Network (CAN) data bus network. The SAS relays switch status data from the following:



3605675

- Horn Switch
- Right Steering Wheel Switch
- Left Steering Wheel Switch
- Remote Radio Switches
- Multi-Function Switch, which includes:
  - Headlamp Beam Selection
  - Front and Rear Wipers
  - Turn Signals

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Steering Angle Sensor (SAS) is part of the clockspring. The SAS detects steering wheel direction, angular magnitude, and rotational velocity, and transmits this data over the vehicle high speed serial communication bus (CAN-C). The SAS is a LIN bus master for the Multi Function Switch (MFS), and for switches that are mounted on the steering wheel (except for cruise control switches). The SAS is the gateway for the LIN bus data, and will transmit this data (switch status, including front wiper, turn signal, cruise control, EVIC) to the CAN-C bus. The SAS shall go into a “Sleep Mode,” with ignition off, and shall “Wake Up” and transmit switch position when the flash to pass and horn functions are actuated. The SAS has dedicated inputs for the decoding of the cruise control switch functions. The cruise control switches are resistor multiplexed (RMUX), and are a “Dual Ladder” type of design. The SAS has primary and backup microprocessors (Master and Slave) to calculate steering angle and cruise control switch functionality. The SAS is able to detect a faulted condition and set a Diagnostic Trouble Code and transmit a Signal Not Available (SNA). The MFS and steering wheel LIN communications do not require redundant calculations. The clockspring portion of this assembly provides circuitry for the steering wheel mounted switches, and the driver airbag inflators.

The steering wheel rotational direction message that the SAS sensor sends out across the CAN-C is one of the following: counterclockwise is positive and clockwise is negative. The neutral or centered position is with the front wheels straight and the steering wheel at top dead center. Rotating the wheel to the left sends a positive value across the CAN-C and rotating the wheel to the right sends a negative value.

The SAS provides steering angle input data to the Electronic Stability Control (ESC) system when the ignition switch is in RUN Position.

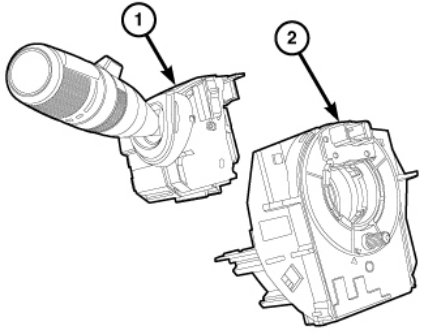
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

This vehicle is equipped with a Steering Column Control Module (SCCM), which combines the following components in a single assembly to ease manufacturing complexity:



3605373

- **Clockspring** - The clockspring (2) is completely concealed beneath the shrouds at the top of the steering column, just below the steering wheel. The clockspring also includes a Steering Angle Sensor (SAS) that is secured to the back of the clockspring housing and is serviced only as a unit with the clockspring. The clockspring housing is constructed of molded black plastic and is secured to the steering column by three screws. (Refer to 10 - Restraints/CLOCKSPRING - Description) .
- **Multifunction Switch** - The only visible component of the multifunction switch (1) is the control stalk, which includes a control sleeve or ring and a control knob that extend through the shrouds on the left side of the steering column. The switch housing and control stalk are constructed of molded black plastic. A single integral latch feature and slide tabs on the switch housing engage channels and a striker that are integral to the left side of the mounting bracket that is integral to the clockspring, which is secured at the top of the steering column, just below the steering wheel. The multifunction switch includes an integral Local Interface Network (LIN) data bus slave node. The multifunction switch is available for separate service replacement. (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps /Lighting - Exterior/SWITCH, Multifunction - Description) .
- **Steering Angle Sensor** - The Steering Angle Sensor (SAS) is completely concealed on the back of the clockspring housing beneath the shrouds at the top of the steering column. The SAS housing is constructed of molded black plastic and is serviced only as a unit with the clockspring. The SAS includes an integral Local Interface Network (LIN) data bus master node and is also a gateway to the Controller Area Network (CAN) data bus network. (Refer to 05 - Brakes/Electrical/SENSOR, Steering Wheel Angle - Description) .

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

The Steering Control Module (SCM) is internal and integral to the Steering Angle Sensor (SAS), which is integral to the clockspring for this vehicle. (Refer to 10 - Restraints/CLOCKSPRING - Installation) .

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The components of the Steering Column Control Module (SCCM) each have one or more integral connector receptacles that connect them to each other and to the vehicle electrical system through dedicated take outs and connectors of the instrument panel wire harness. For additional details, see the service information covering the individual SCCM component as follows:

- **Clockspring** - (Refer to 10 - Restraints/CLOCKSPRING - Operation) .
- **Multifunction Switch** - (Refer to 08 - Electrical/8L - Lamps and Lighting/Lamps/Lighting - Exterior/SWITCH, Multifunction - Operation) .
- **Steering Angle Sensor** - (Refer to 05 - Brakes/Electrical/SENSOR, Steering Wheel Angle - Description) .

The hard wired circuits between components related to the SCCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the SCCM electronic components or the electronic controls and communication between modules and other devices that rely upon inputs from the SCCM components to provide some features. The most reliable, efficient and accurate means to diagnose the SCCM components or the electronic controls and communication related to SCCM component operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

The Steering Control Module (SCM) is internal and integral to the Steering Angle Sensor (SAS), which is integral to the clockspring for this vehicle. (Refer to 10 - Restraints/CLOCKSPRING - Removal) .

2014 Dodge JC - DODGE JOURNEY

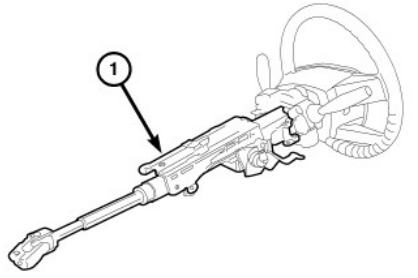
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

This vehicle is equipped with a tilt/telescoping type steering column (1). It is of the Corporate Low Pivot Column (CLPC) design family. When the lever is in the released position, the column can be tilted or telescoped manually.

The steering column is designed to be serviced only as a complete assembly if an internal component is found to be defective. The shaft, bearings and intermediate shaft are all serviced with the column.

The major components on the steering column assembly are:

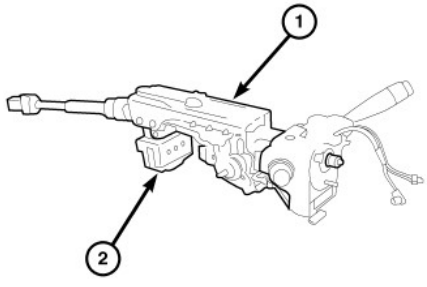


81a63f65

- Clockspring (Integral part of Steering Column Control Module (SCCM))
- Driver Airbag
- Multi-Function Switches (left and right)
- Tilt Lever
- Shrouds
- Steering Wheel

These components can be serviced without removal of the steering column from the vehicle. Refer to the appropriate section for servicing these components separately.

A theft deterrent devise, shaft lock module (2), is located on some steering columns (1). The electronically controlled shaft lock module locks the steering column shaft in place when the key is removed from the ignition key cylinder.



81a63f93

Fuel Delivery: | **Fuel:**

INSPECTION

Inspect the column for damage any time the driver airbag has deployed.

Lower the steering column from its mount and inspect the column collapse feature. If the rearmost rivets (1) have dislodged from top of their mounting pads (2), into the mounting bracket slots, the column must be replaced. **NO attempt should be made to return the rivets to the top of the pads.**

If any physical damage or stress cracks are present on the column, the column must be replaced.

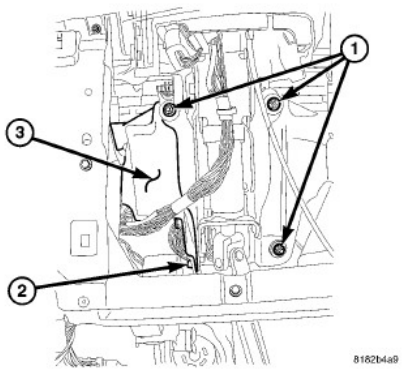
LEFT-HAND DRIVE

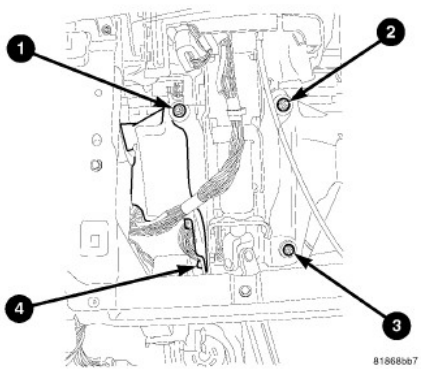
Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: When installing a tilt column, do not release the tilt lever from the locked position until after the column is installed on the instrument panel.

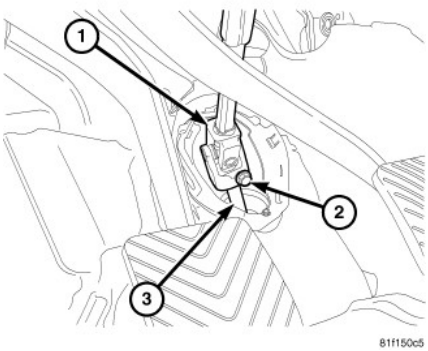


1. Install the steering column through the steering column opening.
2. Raise the column onto the mounting studs and install the three mounting nuts (1) on the studs and the one bolt (2).

NOTE: When tightening the fasteners in the following step, make sure there is no gap between the column flange and the instrument panel support at bolt (4).

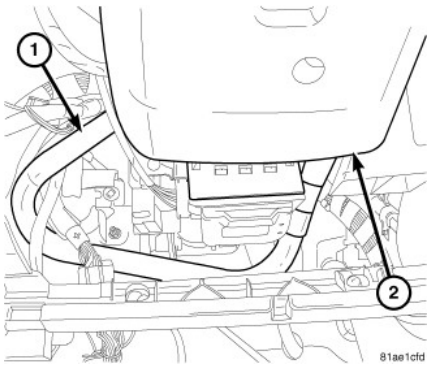


3. Starting with the left upper nut and proceeding in a clockwise tightening sequence ending at the bolt (left lower), tighten all four mounting fasteners to 28 N·m (21 ft. lbs.).
4. Verify the front wheels of vehicle are in the STRAIGHT-AHEAD position.

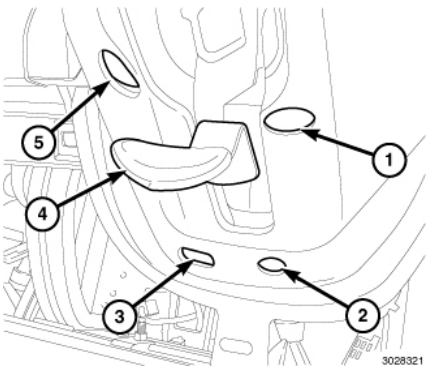


5. Collapse the intermediate shaft (2). Center the intermediate shaft coupling (1) over the steering gear pinion shaft (3), then slide the intermediate shaft onto the steering gear pinion shaft.
6. Install the intermediate shaft coupling bolt (2). Tighten the bolt to 42 N·m (31 ft. lbs.).
7. Position the sound deadening insulation and floor carpet back into place.

8. If equipped, Install the clutch pedal blocker (1) using three mounting screws.

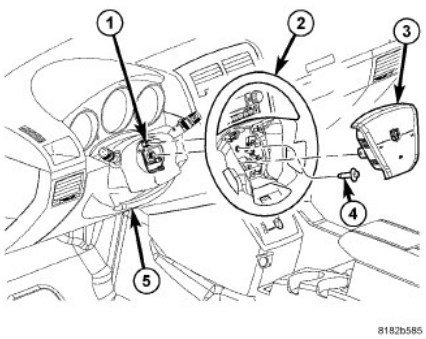


9. Push the tilt lever (4) downward (released position).
10. Install the lower shroud over the tilt lever and onto the column.
11. Install the upper shroud onto the lower shroud, clipping the shrouds to one another.
12. Install the three screws (1, 2, 5) attaching the lower shroud to the steering column.
13. Snap the gap hider clips (3) into the lower shroud.
14. Position the column tilt at the full-upward position.
15. Push the tilt lever (4) upward, locking the column in place.



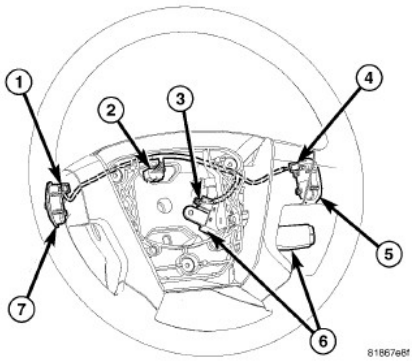
CAUTION: **When installing the steering wheel, the clockspring must be centered in its travel to avoid overextending the clockspring inner parts, causing the clockspring to become inoperative. If removed and handled properly using the correct procedures, it should be in the “centered” position. If there is any question as to whether the clockspring is in the “centered” position of travel, perform the clockspring centering procedure before proceeding. .**

NOTE: Do not reuse the old steering wheel bolt, a new bolt must be used every time.

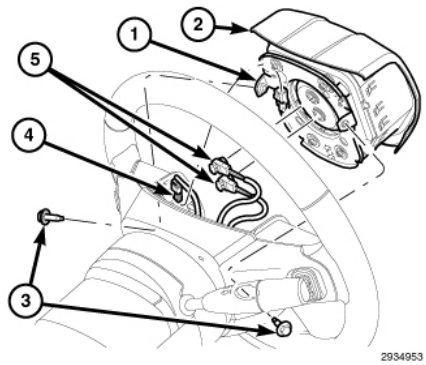


16. Install the steering wheel (2) and a **NEW** retaining bolt (4). Tighten the steering wheel retaining bolt to 50 N·m (37 ft. lbs.) (Refer to 19 - Steering/Column /WHEEL, Steering - Installation) .

17. Connect the wiring connector (2) at the clockspring.



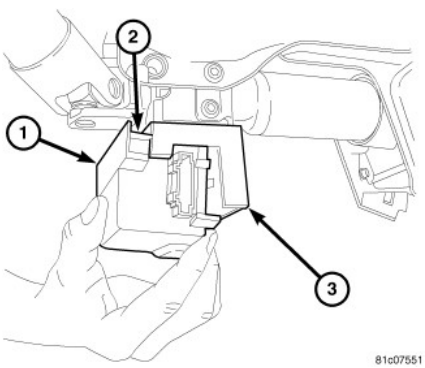
18. Install the driver airbag (2). (Refer to 10 - Restraints/AIR BAG, Driver - Installation)



WARNING: **Do not connect the battery ground cable without following the proper procedure as indicated in the following step. Personal injury or death may result if the Airbag System Test is not performed first.**

19. Reconnect the battery ground terminal following the Airbag System Test found in Restraints (Refer to 10 - Restraints - Diagnosis and Testing) .

20. If the steering column being installed requires the installation of a shaft lock module, perform the following:



a. If not present, insert the ignition key into the ignition lock cylinder. This will move the shaft lock module locking bolt to the unlocked position. Leave the key in the lock cylinder while the shaft lock module service is being completed.

b. Make sure the wiring harness connector is properly connected to the module.

c. Align the engagement and slide tabs (2) on the shaft lock module housing (1) with the slots and channels in the mounting bracket (3) on the steering column.

d. Carefully slide the module toward the top (steering wheel end) of the column until it is in mounted position and the spring clips on the module have engaged the bracket, locking it in place.

NOTE: If a NEW shaft lock module has been installed, a Wireless Ignition Node (WIN) must also be installed, then a diagnostic scan tool MUST be used to initialize the new module before the vehicle can be operated (perform WIN Verification Test). (Refer to 08 - Electrical/8Q - Vehicle Theft Security - Standard Procedure)

21. Install the steering column cover reinforcement (1) using the four mounting screws (2).

22. Install the steering column opening cover (Refer to 23 - Body/Instrument Panel/COVER, Steering Column Opening - Installation) .

23. Test the operation of the all column mounted components. If applicable, reset the radio and the clock as necessary.

24. Road test the vehicle to ensure proper operation of the steering system.

Fuel Delivery: | **Fuel:**

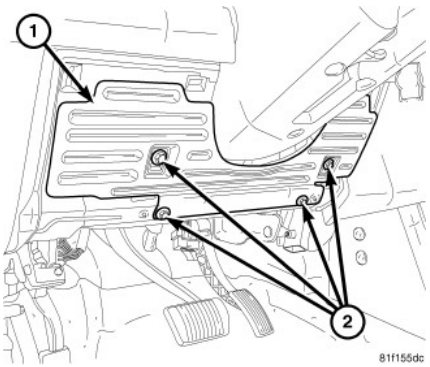
LEFT-HAND DRIVE

Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: Before proceeding, (Refer to 19 - Steering/Column - Warning) .

1. Remove the steering column opening cover (Refer to 23 - Body/Instrument Panel/COVER, Steering Column Opening - Removal) .
2. Remove the steering column cover reinforcement mounting screws (2). Remove the steering column cover reinforcement (1).



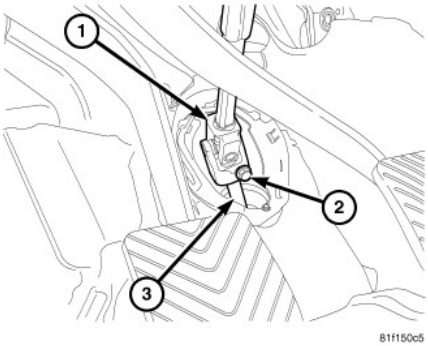
NOTE: If equipped with a shaft lock module, the module cannot be removed from the steering column while the locking bolt is in the locked position without irreversibly damaging the column. Before attempting service, the ignition key must be inserted into the ignition lock cylinder. Once inserted, rotate the steering wheel from side to side. If the steering wheel can be rotated, the locking bolt is in the unlocked position. Leave the key in the ignition lock cylinder until shaft lock module removal has been completed.

3. If equipped with a shaft lock module (2), perform the following steps.

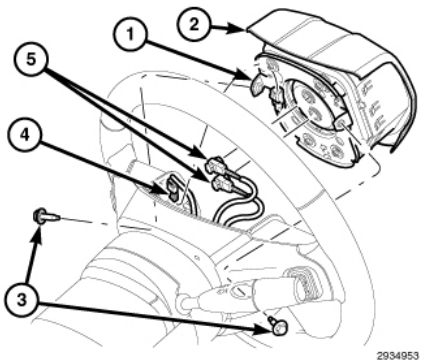
   a. Insert the ignition key into the ignition lock cylinder. This will move the shaft lock module locking bolt to the unlocked position. Leave the key in the lock cylinder while the shaft lock module is being removed.
   b. Insert a suitable drift or pin punch (no more than 4 mm (5/32 in.) in diameter) into each release hole (1) on the module mounting bracket. Insert each drift or punch until it bottoms and leave in place. This will depress the two spring clips that secure the shaft lock module to the mounting bracket.
   c. Slide (and wiggle) the module toward the base of the column far enough to disengage the module from the mounting bracket.
   d. Remove the module from the steering column.
   e. Leave the wiring connector in place, but support the module to keep it away from the column and avoid wiring harness overextention.

WARNING: **When an undeployed airbag module is to be removed from the vehicle, first disconnect the battery ground cable and isolate it. Allow the system capacitor to discharge for a minimum of two minutes before starting any removal.**

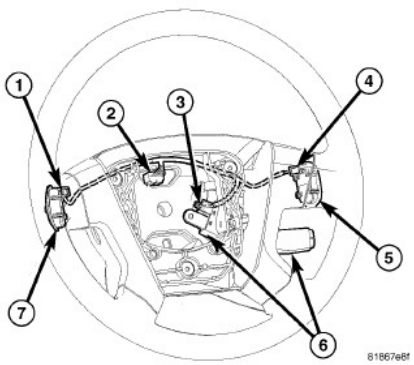
4. Disconnect the negative (-) cable from the battery and isolate the cable.
5. Reposition the floor carpeting and sound deadening insulation to access the intermediate shaft coupling (1) at the base of the column.
6. Place the front wheels of the vehicle (and steering wheel) in the STRAIGHT-AHEAD position.
7. Remove the intermediate shaft coupling bolt (2). **Do not separate the intermediate shaft coupling (1) from the steering gear pinion shaft (3) at this time.**



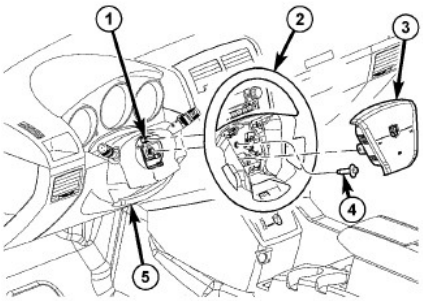
8. Return the front wheels of vehicle (and steering wheel) to the STRAIGHT-AHEAD position.
9. Remove the driver airbag (2) (Refer to 10 - Restraints/AIR BAG, Driver - Removal) .



10. Disconnect the wiring connector (2) at the clockspring.

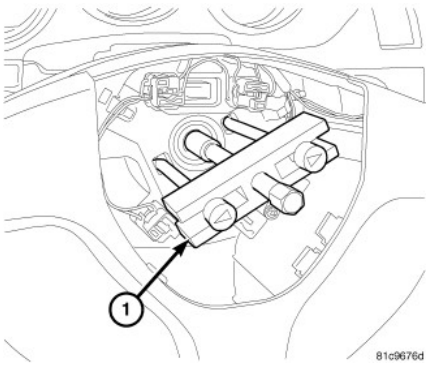


11. While holding the steering wheel firmly in place, remove the steering wheel retaining bolt (4) from the steering column shaft.



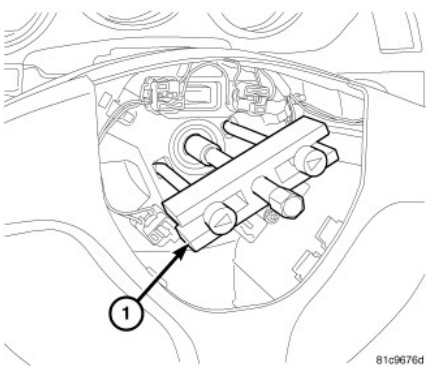
CAUTION: **Do not bump or hammer on the steering wheel or steering column shaft when removing the steering wheel.**

12. Install an appropriate wheel puller with hooked legs (1) on the steering wheel over the steering shaft (Refer to 19 - Steering/Column/WHEEL, Steering - Removal) .



CAUTION: **Do not attempt to rotate the clockspring rotor once the steering wheel is removed. The clockspring must remain centered in its travel to avoid overextending the clockspring inner parts, causing the clockspring to become inoperative. If removed and handled properly using the correct procedures, it should remain in the “centered” position. If there is any question as to whether the clockspring is in the “centered” position of travel, perform the clockspring centering procedure before installing the steering wheel .**

13. While holding the steering wheel firmly in the STRAIGHT-AHEAD position, release the steering wheel from the steering column shaft splines using the wheel puller (1). Remove the steering wheel from the column.

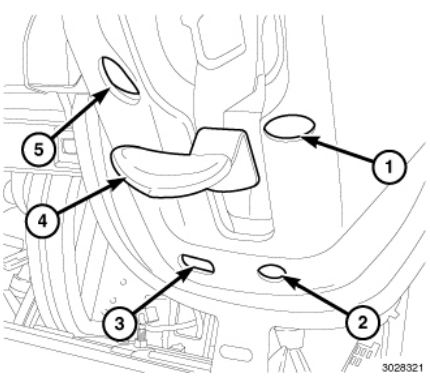


14. Push the tilt lever (4) downward to the released position.

15. Remove the three screws (1, 2, 5) attaching the lower shroud. After removing the screws, un-clip the upper and lower shrouds from one another by applying hand pressure along the seams where the shrouds connect on the sides.

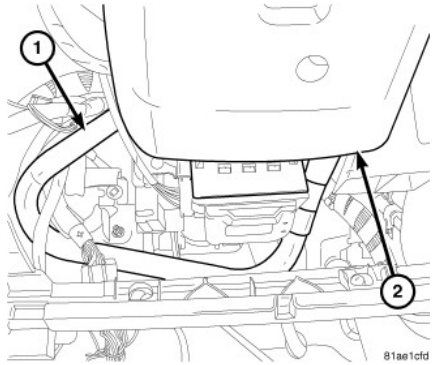
16. Separate the gap hider clips (3) from the lower shroud.

17. Remove the upper and lower shrouds.

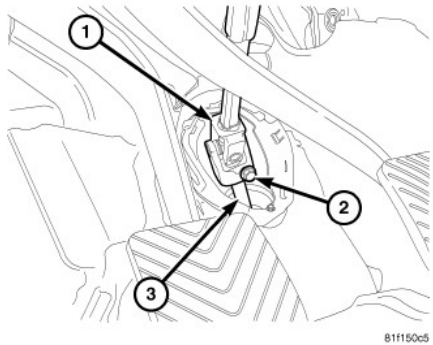


18. Push the tilt lever upward, locking the column in place.

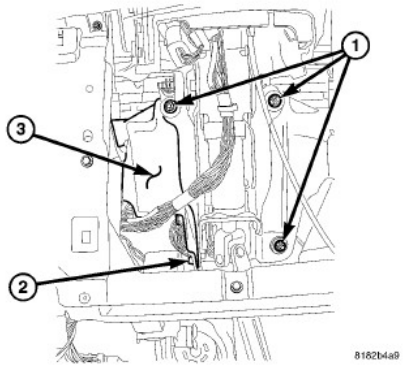
19. If equipped, remove the three clutch pedal blocker mounting screws, then remove the blocker (1).



20. Separate the intermediate shaft coupling (1) at the base of the column from the steering gear pinion shaft (3).



NOTE: If the same steering column is to be reinstalled, clamp the tilt lever to lock the column in place so that it can be easily reinstalled in the same orientation.



21. Remove the one mounting bolt (left lower) (2) attaching the steering column to the instrument panel (3).

22. Remove the three mounting nuts (1) attaching the steering column to the instrument panel (3).

23. Remove the steering column from the vehicle.

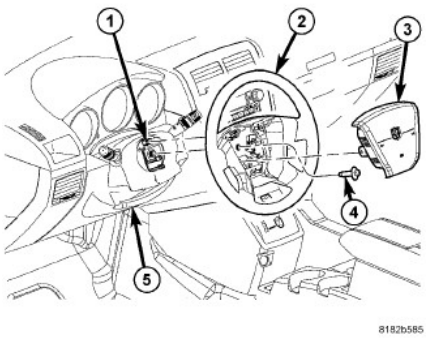
INSTALLATION

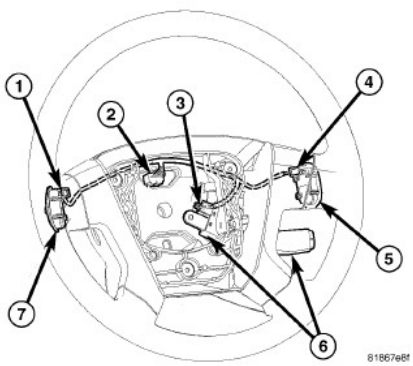
Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **Do not install the steering wheel onto the shaft of the steering column by driving it onto the shaft.**

NOTE: Do not reuse the old steering wheel bolt, a new bolt must be used every time.



1. Confirm that:
   a. The front wheels are in the STRAIGHT-AHEAD position.
   b. The turn signal stalk is in the NEUTRAL position.
2. Align the wide mounting spline of the steering wheel (2) with the missing spline area of the steering column shaft (1) and push the wheel onto the shaft. Make sure the clockspring lines up with the back of the wheel and does not bind.
3. Install a **NEW** steering wheel retaining bolt (4) and tighten 50 N·m (37 ft. lbs.).
4. Connect the wiring connector (2) at the clockspring.



5. Install the driver airbag (3) (Refer to 10 - Restraints/AIR BAG, Driver - Installation) .

WARNING: **Do not reconnect the battery without first performing the Airbag System Test procedure . Failure to perform the Airbag System Test may result in accidental airbag deployment and serious or fatal injury.**

6. Reconnect the battery using the Airbag System Test procedure (Refer to 10 - Restraints - Diagnosis and Testing) .

7. Verify vehicle and system operation.

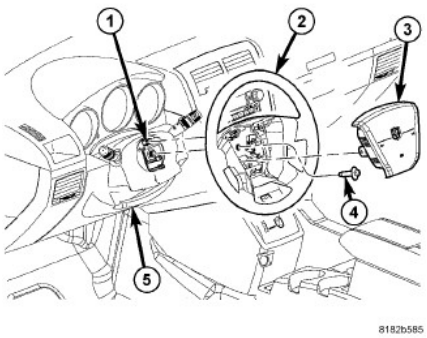
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

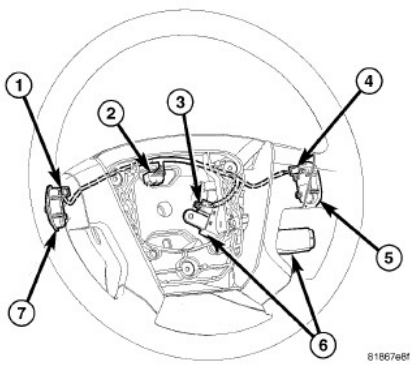
WARNING:

- **Do not place a non-deployed airbag face down on a hard surface. The airbag will propel into the air if accidentally deployed. Failure to follow this instruction may result in possible serious or fatal injury.**
- **Disconnect and isolate the battery negative (ground) cable before beginning steering wheel removal or installation. This will disable the airbag system. Failure to follow this instruction may result in accidental airbag deployment and possible serious or fatal injury.**
- **Allow the airbag system capacitor to discharge for two minutes before removing the steering wheel or any airbag system component. Failure to follow this instruction may result in accidental airbag deployment and possible serious or fatal injury.**

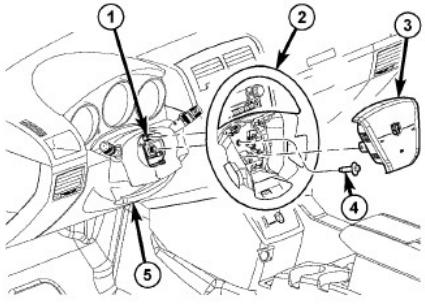
1. Adjust the steering wheel so that the tires are in the STRAIGHT-AHEAD position.
2. Disconnect and isolate the negative battery cable.
3. Remove the driver airbag (3) (Refer to 10 - Restraints/AIR BAG, Driver - Removal) .



4. Disconnect the wiring connector (2) at the clockspring.



5. Holding the steering wheel (4) firmly in place, remove the steering wheel retaining bolt (4) from the steering column shaft.



CAUTION: **Do not bump or hammer on the steering wheel or steering column shaft when removing the steering wheel.**

NOTE: The jaws should point outward from the center of the steering wheel for removal.

6. Install Gear Puller L-4407A (1) and OTC® 7929A Steering Wheel Puller Leg Set or equivalent and loosen the steering wheel.

CAUTION: **Do not attempt to rotate the clockspring rotor once the steering wheel is removed. The clockspring must remain centered in its travel to avoid overextending the clockspring inner parts, causing the clockspring to become inoperative. If removed and handled properly using the correct procedures, it should remain in the "centered" position. If there is any question as to whether the clockspring is in the "centered" position of travel, perform the clockspring centering procedure before installing the steering wheel.**

7. Holding the steering wheel firmly in the STRAIGHT-AHEAD position, release the steering wheel from the steering column shaft splines using the wheel puller (1). Remove the steering wheel from the column.

WARNING

WARNING: **Safety goggles should be worn at all times when working on steering columns.**

WARNING: **Before beginning any service procedure that involves removing the air bag: Remove and isolate the negative (-) battery cable (ground) from the vehicle battery. This is the only sure way to disable the air bag system. Failure to do this could result in accidental air bag deployment and possible personal injury.**

WARNING: **The air bag system is a sensitive, complex electro-mechanical unit. Before attempting to diagnose, remove or install the air bag system components you must first disconnect and isolate the battery negative (ground) cable. Failure to do so could result in accidental deployment of the air bag and possible personal injury. The fasteners, screws, and bolts, originally used for the air bag components, have special coatings and are specifically designed for the air bag system. They must never be replaced with any substitutes. Anytime a new fastener is needed, replace with the correct fasteners provided in the service package or fasteners listed in the parts books. Before servicing a steering column equipped with an air bag,**

WARNING: **When handling an undeployed air bag during servicing of the steering column, the following precautions should be observed:**

- **At no time should any source of electricity be permitted near the inflator on the back of the air bag.**
- **When carrying a live air bag, the trim cover should be pointed away from the body to minimize injury if the air bag should accidently deploy.**
- **If the air bag is placed on a bench or other surface, the plastic cover should be face-up to minimize movement, in case of accidental deployment.**

CAUTION: **Disconnect negative (ground) cable from the battery before servicing any column component.**

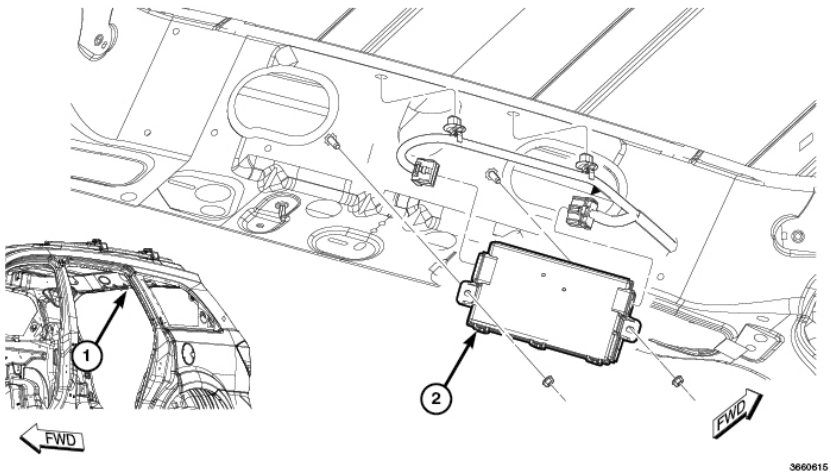
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION



The RF Hub (2) is located above the headliner at the tailgate opening (1). The Remote Start Antenna (if equipped) is connected directly to it.

The electronic functions of the Radio Frequency Hub (RF-Hub) supports or controls the following:

- **Immobilizer** - Kills the engine when there is an unauthorized attempt to steal the vehicle.
- **Remote Keyless Entry** - This feature allows the FOBIK to lock, unlock or activate the Panic alert. If the vehicle is equipped with the Remote Start feature the operating distance is approximately 91.5 meters (300 feet). If it is not equipped with Remote Start the operating distance is approximately 20 meters (66 ft.).
- **Keyless Go** - With an authorized FOBIK in the vehicle this allows the operator to start and run the vehicle by pressing the Start/Stop Button (SSB) on the Keyless Ignition Node (KIN).
- **Passive Entry** - The Passive Entry feature of the RF-Hub allows the operator, with an authorized FOBIK in their possession, to open a locked front door or liftgate by simply lifting the handle. The FOBIK must be within approximately 1.5 meters (5 ft.) of the door/liftgate. Once all the doors and the liftgate are closed, the operator can lock the vehicle by pressing the lock switch on the door handle.
- **Electronic Steering Column Lock** - The ELV/ESCL is only used on some export vehicles. When there is an authorized FOBIK in the front seat area, the Steering Column Lock will unlock the column when the Start/Stop button on the KIN is pressed to the Run position and will lock the column when the button is pressed to the Stop position.
- **Keyless Ignition Node (KIN) dimming control** - The RF-Hub controls the illumination to the Keyless Ignition Node (KIN).
- **Remote Start** - This feature allows the operator to start or stop the engine from outside the vehicle. The FOBIK cannot be farther from the vehicle than approximately 91.5 meters (300 ft.).

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Radio Frequency Hub Module (RFHM) (also known as the RF Hub/RFH) is an integrated receiver (or base station) in the vehicle that communicates with other electronic modules in the vehicle over either the Controller Area Network (CAN) data bus or a private serial bus to support the following standard and optional vehicle features or systems.

- **Brake Transmission Shift Interlock System (for automatic Transmission only)** - The RFHM contains the controlling logic for the Brake Transmission Shift Interlock (BTSI) solenoid. The RFHM monitors the key postion from the IGnition Node Module (IGNM) received over a private serial bus, hard wires brake input as well as inputs received over the CAN data bus to perform the BTSI solenoid control functions.
- **Ignition Systems** - Depending upon how the vehicle is equipped, Rotary Switch system or Keyess GO system. For rotary system, IGnition Node Module IGNM coil communicate with FOBIK through LF signals (125 KHz) then communicates it to RFHM through a private serial bus, then RFHM sends CAN data bus to BCM for IGNTION status after valid key is verified. The RFHM also contains the controlling logic for the KG (KIN) back lighting features.
- **Passive Entry** - If Smart door handles or exterior deck lid release switch is activated, RFHM fires and monitors LF signals from five Low Frequency (LF) antennas which wake up and communicate with the FOBIK, and RF signals from FOBIK to verify the key, , if valid key is recognized by RFHM then RFHM sends CAN data bus to BCM to lock or unlock the vehicle.
- **Remote Keyless Entry** - The RFHM is an RF receiver that monitors RF signals from Remote Keyless Entry (RKE) transmitter (FOBIK) and relays the appropriate electronic messages BCM module over the CAN data bus to support the features of RKE functions.
- **Remote Start System** - The RFHM is an RF receiver that monitors RF signals received through the remote start antenna (longer range) from the Remote Keyless Entry (RKE) transmitter or the Passive Entry Keyless Go (PEKG) FOBIK and relays the appropriate electronic messages to BCM over the CAN data bus to support all RKE functions including optional remote start function.
- **Sentry Key Immobilizer System** - RFHM uses a new high security encryption system called “Advanced Encryption Stanandard –AES” for Sentry Key Immobilizer System (SKIS). The new system marries FOBIKs, RFHM, BCM, ELV (if so equipped” and ECM with unique secret keys for each vehicle. Swapping parts ARE NOT ALLOWED in the new system, FOBIK are not allow to program for more than one Vehicle. Replacing any part of the system shall be done only in Chrysler authorize dealers using Chrysler diagnostic tool.
- **Vehicle Theft Alarm System** - The RFHM is an RF receiver that monitors RF signals received from the Remote Keyless Entry (RKE) transmitter or the Passive Entry Keyless Go (PEKG) FOB with Integrated Key (FOBIK) and relays the appropriate electronic messages to other electronic modules in the vehicle over the CAN data bus to support the features of the optionnal VTA system.

The RFHM is connected to a fused B(+) circuit and has a path to a clean ground at all times. These connections allow it to remain functional regardless of the ignition switch status. Any input to the RFHM that controls a vehicle system function that does not require that the ignition switch status be ON such as depressing a button on an RKE or FOBIK transmitter, prompts the RFHM to wake up and transmit on the CAN data bus.

The Body Control Module (BCM) stores and compares vehicle configuration data with the RFHM as well as with other Electronic Control Units (ECU) in the vehicle. This process is referred to as PRogramming Of Configuration of Systems Integrated (PROCSI) (also known as PROXI). If a configuration mismatch is detected, the BCM sets a DTC. A configuration mismatch DTC will require the performance of a Restore BCM PROXI Configuration routine, or a PROXI Configuration Alignment routine using a diagnostic scan tool.

RFHM uses On-Board Diagnostics (OBD) to monitor all of the Functions and circuits it controls, then sets active and stored Diagnostic Trouble Codes (DTC) for any monitored function faults it detects. RFHM will also send electronic message requests to the Instrument Cluster (IC) (also known as the Instrument Panel Cluster/IPC) through the gate way module (BCM) for the display of certain textual warning messages related to some detected functions conditions or faults.

The hard wired inputs and outputs of the RFHM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the RFHM electronic controls or the communication between modules and other devices that provide some features of the RFHM-controlled systems. The most reliable, efficient and accurate means to diagnose the RFHM or the electronic controls and communication related to RFHM-controlled systems operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

RADIO FREQUENCY HUB MODULE INITIALIZATION - EXPORT WITH COLUMN LOCK MODULE

CAUTION: **On vehicles equipped with the optional export premium Vehicle Theft System, when either the Radio Frequency Hub RF-Hub) or the shaft lock module (also known as Elektrische Lenksäulen Verriegelung/ELV or Electric Steering Column Lock/ESCL) is replaced with a new unit, the existing RF-Hub or ELV/ESCL MUST also be replaced with a new unit. In other words, any time either the RF-Hub or the ELV/ESCL is replaced with a new unit, BOTH the RF-Hub and the ELV/ESCL MUST be replaced with new units, WITHOUT EXCEPTION. Following replacement of BOTH the RF-Hub and the column lock module/ELV/ESCL, the two modules MUST be initialized using diagnostic scan tool routines in the EXACT SEQUENCE that follows. Failure to follow this sequence may result in BOTH the new RF-Hub and the new ELV/ESCL being rendered unusable, requiring BOTH units to be replaced a second time.**

NOTE: Do not put a laptop or any wireless device (cell phones, audio devices etc.) near the top of the center console (the RKE antenna is located below the center console).

1. After both the RF Hub and the ELV/ESCL have been replaced with new units, connect the diagnostic scan tool to the Data Link Connector (DLC).
2. Turn the ignition ON.
3. Navigate to the RF Hub in the ECU View of the diagnostic scan tool.
4. Turn the ignition OFF.
5. Put all the FOBIKs used in this vehicle on the front seat away from the console.
6. With the scan tool select: **Program Ignition FOBIKs** in the **Miscellaneous Functions** menu and follow the instructions on the screen.

   NOTE: When programming a FOBIK, have it in your hand resting on the console.

7. After all of the FOBIKs have been programmed, run the **RF Hub Replace** routine.
8. Turn the ignition ON.
9. Run the **ELV Replaced** routine, also found under the **Miscellaneous Functions** menu item of the **RF Hub** in the **ECU View** of the diagnostic scan tool.
10. Turn the ignition to the OFF position, wait 30 seconds, then cycle the ignition back to the ON/RUN position.
11. Verify that the ELV locks the steering column when the ignition is turned OFF and unlocks the steering column when the ignition is turned ON.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

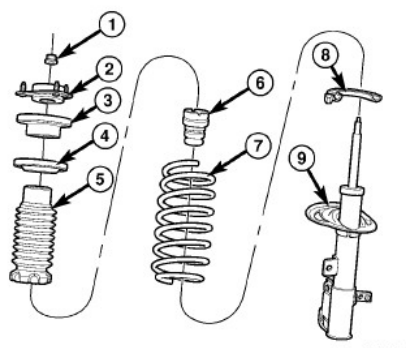
DESCRIPTION

A Macpherson type design strut assembly is used in place of the traditional front suspension upper control arm and upper ball joint. The bottom of the strut mounts directly to the steering knuckle using two attaching bolts and nuts going through the strut clevis bracket and knuckle. The top of the strut mounts directly to the strut tower of the vehicle using the three threaded studs on the strut assembly's upper mount.

The strut assembly includes the following components:

- Upper mount (2)
- Bearing and upper spring seat (3)
- Upper spring isolator (4)
- Dust shield (5)
- Jounce bumper (6)
- Coil spring (7)
- Lower spring isolator (8)
- Strut (damper) (9)



Each component is serviced by removing the strut assembly from the vehicle and disassembling it.

Coil springs are rated separately for each corner or side of the vehicle depending on optional equipment and type of vehicle service. If a coil spring requires replacement, be sure that it is replaced with a spring meeting the correct load rating for the vehicle and its specific options.

DISASSEMBLY

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

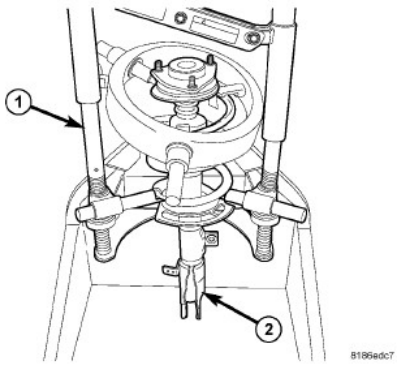
CAUTION: **Do not use any type of pliers on the chrome machined surface of shock/strut rod to assist in the disassembly/assembly of shocks or struts. Use only tools designed to hold the shock/strut rod stationary when servicing shock or strut components.**

NOTE: The strut assembly must be removed from the vehicle for it to be disassembled and assembled. (Refer to 02 - Front Suspension/Front /STRUT, Suspension - Removal)

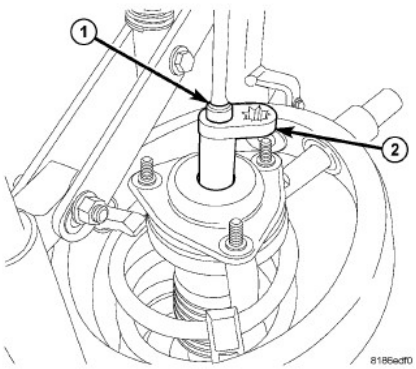
For the disassembly and assembly of the strut assembly, use strut spring compressor, teamPSE tool 223-7400, or the equivalent, to compress the coil spring. Follow the manufacturer's instructions closely.

WARNING: **Do not remove the strut rod nut before the coil spring is properly compressed. The coil spring is held under pressure. The coil spring must be compressed, removing spring tension from the upper mount and bearing, before the strut rod nut is removed.**

1. If both struts are being serviced at the same time, mark both the coil spring and strut assembly according to which side of the vehicle the strut is being removed from.
2. Position the strut assembly (2) in the strut coil spring compressor (1) following the manufacturer's instructions and set the lower and upper hooks of the compressor on the coil spring. Position the strut clevis bracket (2) straight outward, away from the compressor.
3. Compress the coil spring until all coil spring tension is removed from the upper mount and bearing.



CAUTION: **Never use impact or high speed tools to remove the strut rod nut. Damage to the strut internal bearings can occur.**



4. Once the spring is sufficiently compressed, install Strut Nut Wrench (2) 9362 , on the strut rod nut. Next, install a deep socket (1) on the end of the strut rod. While holding the strut rod from turning, remove the nut using the strut nut wrench.

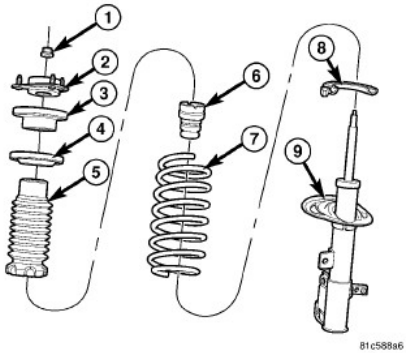
5. Remove the clamp (if installed) from the bottom of the coil spring and remove the strut (damper) (9) out through the bottom of the coil spring.

6. Remove the lower spring isolator (8) from the strut seat.

7. remove the dust shield (5) and jounce bumper (6).

8. Remove the upper strut mount (2) from the top of the bearing and upper spring seat (3).

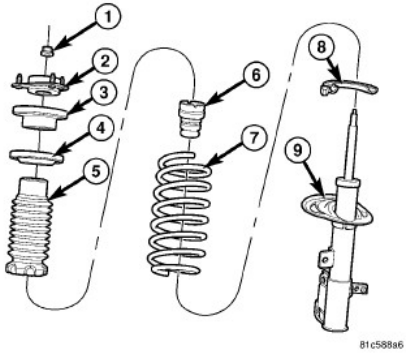
9. Remove the upper spring seat (3) and isolator (4) from the top of the coil spring (5).



NOTE: If the coil spring needs to be serviced, proceed with the next step, otherwise, proceed with Step #11.

10. Release the tension from the coil spring by backing off the compressor drive completely. Push back the compressor hooks and remove the coil spring.

11. Inspect the strut assembly components for the following and replace as necessary:



- Inspect the strut (damper) (9) for shaft binding over the full stroke of the shaft.
- Inspect the jounce bumper (6) for cracks and signs of deterioration.
- Inspect the dust shield (5) for cracks and tears.
- Check the upper mount (2) for cracks and distortion and its retaining studs for any sign of damage.
- Check the bearing and upper spring seat (3) for any binding.
- Inspect the upper and lower spring isolators (4, 8) for material deterioration and distortion.
- Inspect the coil spring (7) for any sign of damage to the coating.

NOTE: For reassembly, (Refer to 02 - Front Suspension/Front/STRUT, Suspension - Assembly) .

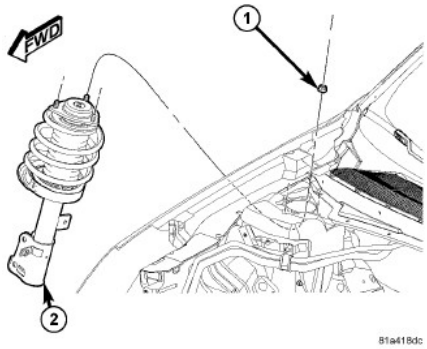
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

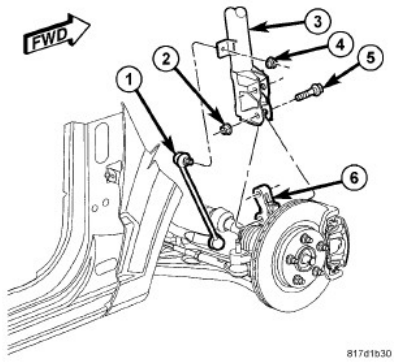
1. Raise the strut assembly (2) into the strut tower, aligning the three studs on the strut assembly upper mount with the holes in strut tower. Install the three mounting nuts (1) on the studs. Tighten the three nuts to 55 N·m (41 ft. lbs.).



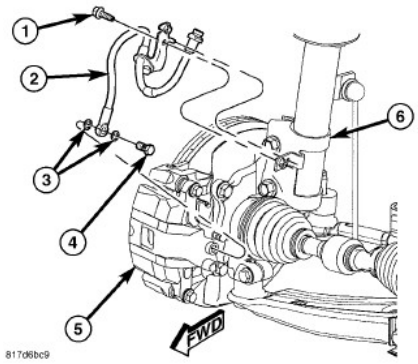
CAUTION: **The strut clevis-to-knuckle bolts (5) are serrated and must not be turned during installation. Install the nuts while holding the bolts stationary in the knuckle.**

2. Position the lower end of the strut assembly (3) in line with the upper end of the knuckle (6), aligning the mounting holes. Install the two attaching bolts (5). Install the nuts (2). While holding the bolts in place, tighten the nuts to 140 N·m (103 ft. lbs.).

3. Attach the stabilizer bar link (1) to the strut (3). Install and tighten the nut (4) while holding the stabilizer bar link stud stationary. Tighten the nut to 100 N·m (74 ft. lbs.).

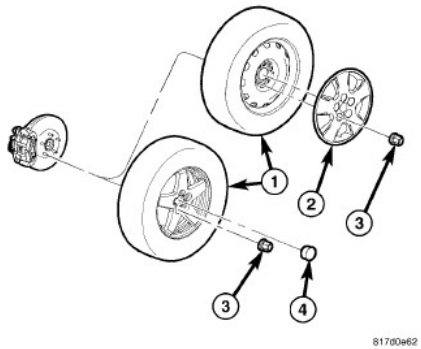


4. Secure the flex hose (2) routing bracket to the strut (6) with the mounting screw (1). Tighten the mounting screw to 13 N·m (120 in. lbs.).



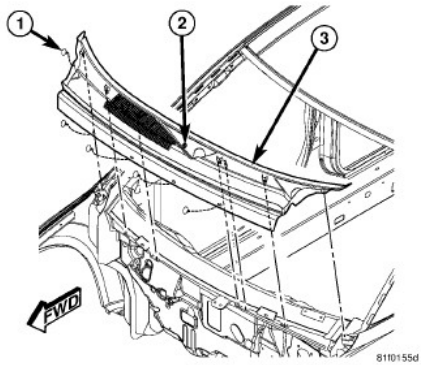
5. Install tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

6. Lower the vehicle.



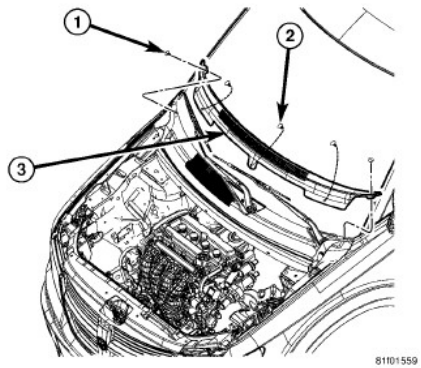
7. Install the cowl screen. Install the push-pins (1) securing the cowl screen to the wheelhouse brace and cowl. Rotate the screw (2) in the center of the cowl screen 90° counterclockwise to lock the screen in place.

8. Install the wiper arms. (Refer to 08 - Electrical/8R - Wipers/Washers/ARM, Wiper - Installation)



9. Install the cowl top screen (3). Install the two push-pins (1) securing the cowl top screen at the ends. Install the remaining push-pins (2).

10. Install the engine appearance cover.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The strut assembly cushions the ride of the vehicle, controlling vibration, jounce and rebound of the suspension.

The coil spring controls ride quality and maintains proper ride height.

The spring isolators isolate the coil spring at the top and bottom from coming into metal-to-metal contact with the upper mounting seat and the strut.

The jounce bumper limits suspension travel and metal-to-metal contact under full jounce condition.

The strut dampens jounce and rebound motions of the coil spring and suspension.

2014 Dodge JC - DODGE JOURNEY

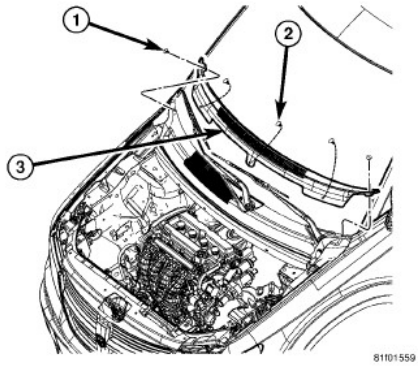
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

REMOVAL

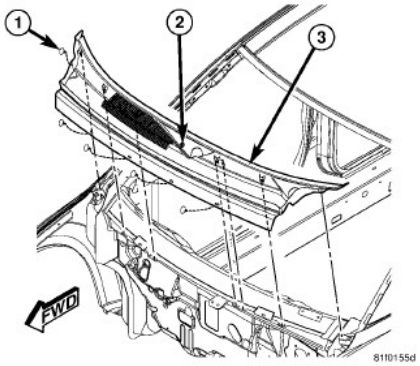
Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: Before proceeding, (Refer to 02 - Front Suspension/Front - Warning) .

1. Remove the engine appearance cover.
2. Remove the two push-pins (1) securing the cowl top screen at the ends. Remove the remaining push-pins (2). Remove the cowl top screen (3).
3. Remove the wiper arms. (Refer to 08 - Electrical/8R - Wipers/Washers/ARM, Wiper - Removal)

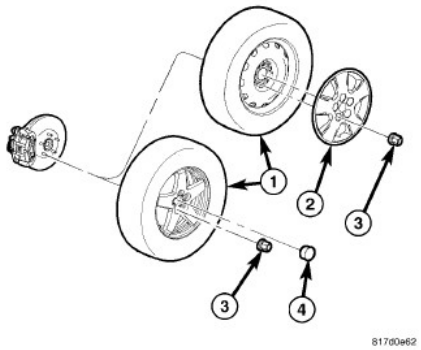


4. Remove the push-pins (1) securing the cowl screen to the wheelhouse brace and cowl. Rotate the screw (2) in the center of the cowl screen 90° clockwise to release the screen. Remove the cowl screen (3).



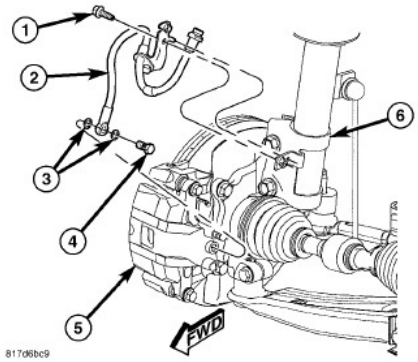
5. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)

6. Remove the wheel mounting nuts (3), then the tire and wheel assembly (1).



NOTE: If both strut assemblies are to be removed, mark the strut assemblies right or left and keep the parts separated to avoid mix-up. Not all parts of the strut assembly are interchangeable side-to-side.

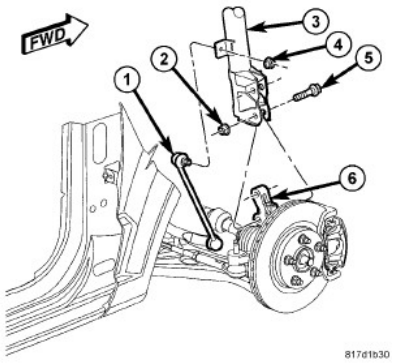
7. Remove the screw (1) securing the flex hose (2) routing bracket to the strut (6).



8. While holding the stabilizer bar link (1) stud stationary, remove the nut (4) securing the link to the strut (3).

CAUTION: **The strut assembly-to-knuckle attaching bolts (5) are serrated and must not be turned during removal. Hold the bolts stationary in the knuckle while removing the nuts, then tap the bolts out using a pin punch.**

9. While holding the bolt heads stationary, remove the two nuts (2) from the bolts (5) attaching the strut (3) to the knuckle (6).



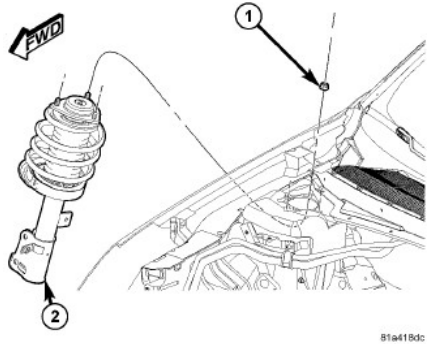
10. Remove the two bolts (5) attaching the strut (3) to the knuckle (6) using a pin punch.

11. Lower the vehicle just enough to open the hood without allowing the tires to touch the floor.

12. Remove the three nuts (1) attaching the strut assembly (2) upper mount to the strut tower.

13. Remove the strut assembly (2) from the vehicle.

14. For disassembly, (Refer to 02 - Front Suspension/Front/STRUT, Suspension - Disassembly) .



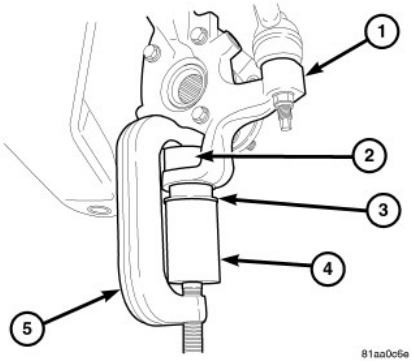
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

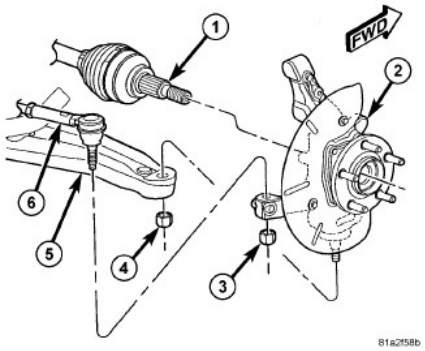
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

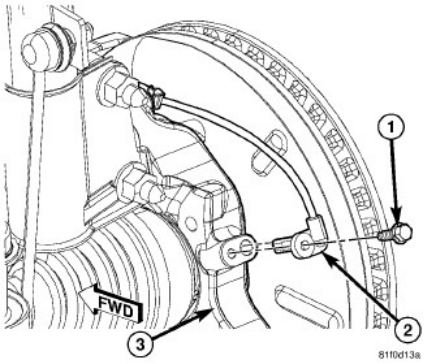
1. Install Installer (2), Special Tool 9964-1 , and Installer (4), Special Tool 9964-2 on Remover/Installer (5), Special Tool 8441-1 . Place a new ball joint (stem down) into Installer 9964-2 .
2. Position the assembly onto the knuckle as shown, then hand tighten the screw-drive.
3. Using hand-tools, tighten the screw-drive forcing the ball joint (3) into the knuckle (1). Continue to install the ball joint until the flange on the ball joint comes to a stop against the bottom of the knuckle.



4. Loosen the screw-drive and remove the tools.
5. Install a NEW snap-ring into the groove in the ball joint using a drift punch.
6. Slide the hub and bearing in the knuckle (2) onto the splines of the half shaft outer C/V joint (1).
7. Insert the lower ball joint stud into the mounting hole in the lower control arm.
8. Install a NEW ball joint stud nut (4). Tighten the nut to 95 N·m (70 ft. lbs.).

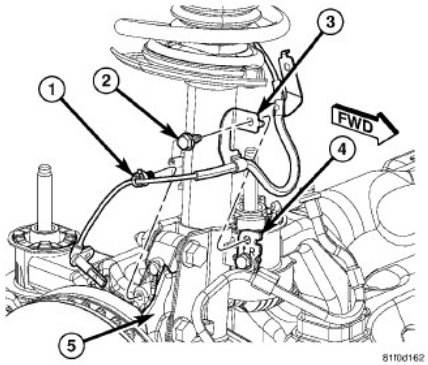


9. Install the wheel speed sensor head (2) into the knuckle (3). Install the mounting screw (1) and tighten it to 12 N·m (106 in. lbs.).

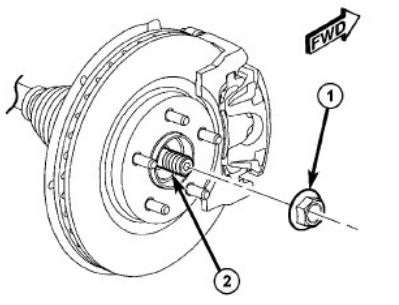


10. Install the routing clip (1) securing the wheel speed sensor cable to the knuckle (5).

11. Install the brake rotor, disc brake caliper and adapter. (Refer to 05 - Brakes/Hydraulic /Mechanical/ROTOR, Brake - Installation)



NOTE: Always install a new hub nut. The original hub nut is one-time use only and should be discarded when removed.



12. Clean all foreign matter from the threads of the half shaft outer C/V joint.

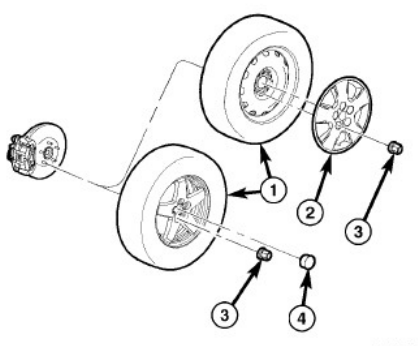
13. Install the hub nut (1) on the end of the half shaft (2) and snug it.

14. While a helper applies the brakes to keep the hub from rotating, tighten the hub nut (3) to 132 N·m (97 ft. lbs.).

15. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

16. Lower the vehicle.

17. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)



2014 Dodge JC - DODGE JOURNEY

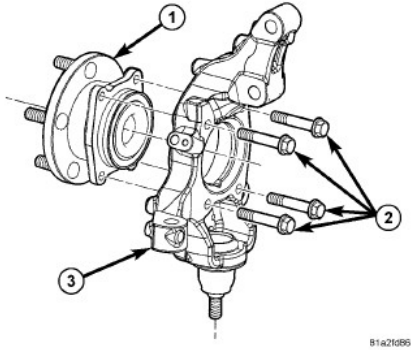
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The front wheel bearing and wheel hub of this vehicle are a one piece sealed unit or hub and bearing unit type assembly.

The hub and bearing (1) is mounted to the knuckle using four mounting bolts (2) and to the axle half shaft using a retaining nut. The center of the hub and bearing is splined to match the outer joint of the axle half shaft.

Each front hub and bearing has five wheel mounting studs on the hub flange for mounting the wheel to the vehicle. The wheel mounting studs are the only replaceable components of the hub and bearing. Otherwise, the hub and bearing is serviced as a complete assembly.



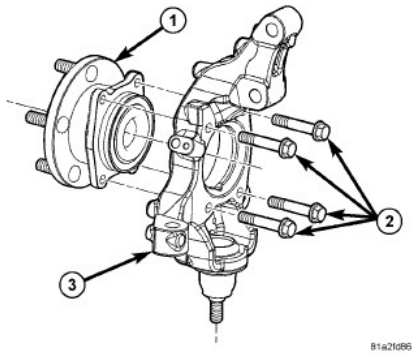
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

INSTALLATION

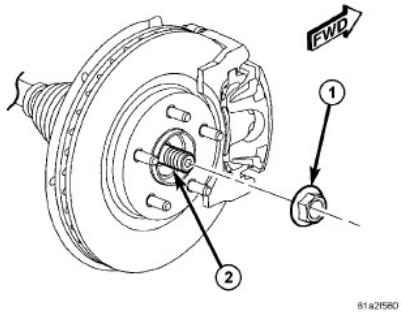
Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Install the hub and bearing (1) by sliding it over the half shaft and into the knuckle.
2. Install the four bolts (2) fastening the hub and bearing (1) to the knuckle (3). Tighten the four bolts to 48 N·m (35 ft. lbs.).
3. Install the brake rotor, disc brake caliper and adapter. (Refer to 05 - Brakes/Hydraulic/Mechanical /ROTOR, Brake - Installation)

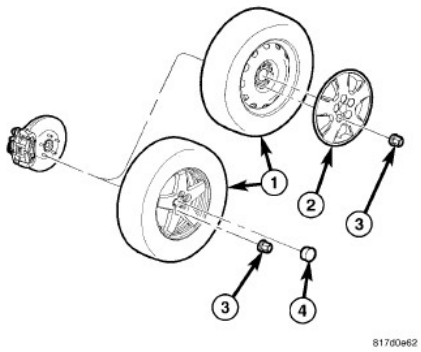


NOTE: Always install a new hub nut. The original hub nut is one-time use only and should be discarded when removed.

4. Clean all foreign matter from the threads of the half shaft outer C/V joint.
5. Install the hub nut (1) on the end of the half shaft (2) and lightly tighten it.
6. While a helper applies the brakes to keep the hub from rotating, tighten the hub nut (1) to 160 N·m (118 ft. lbs.).



7. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).
8. Lower the vehicle.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L

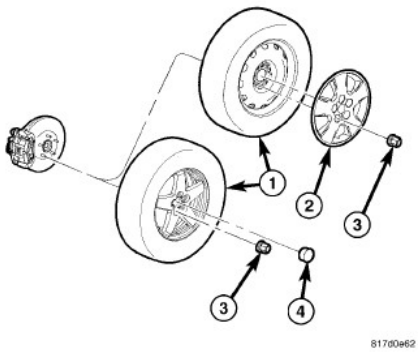
REMOVAL

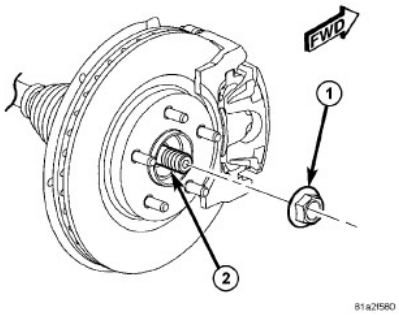
Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: Before proceeding, review all Warnings and Cautions. (Refer to 02 - Front Suspension/Front - Warning)

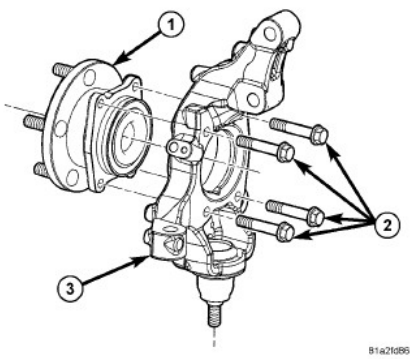
1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)
2. Remove the wheel mounting nuts (3), then the tire and wheel assembly (1).



3. While a helper applies the brakes to keep the hub from rotating, remove the hub nut (1) from the axle half shaft (2).
4. Access and remove the front brake rotor. (Refer to 05 - Brakes/Hydraulic/Mechanical /ROTOR, Brake - Removal)



5. Remove the four bolts (2) fastening the hub and bearing to the knuckle (3).



6. Slide the hub and bearing (1) off the half shaft and out of the knuckle.

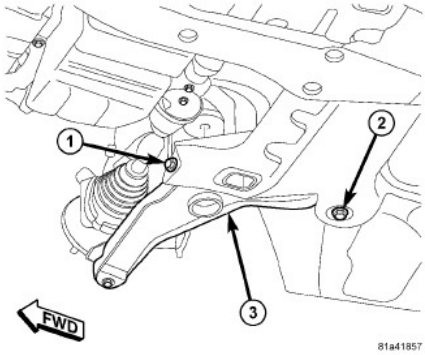
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

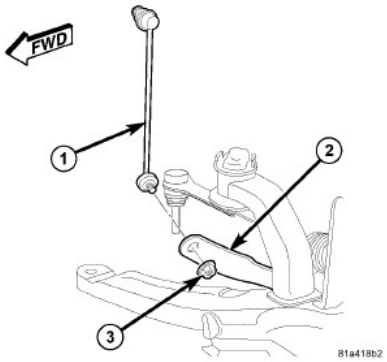
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Place the lower control arm (3) into the front suspension crossmember.
2. Insert the rear bolt (2) up through the crossmember and lower control arm (3). Install the nut on the top-end of the bolt, but do not tighten it at this time.
3. Install, but do not fully tighten, the front bolt (1) attaching the lower control arm (3) to the crossmember.
4. With no weight or obstruction on the lower control arm, tighten the lower control arm **front** mounting bolt (1) to 175 N·m (129 ft. lbs.).



5. With no weight or obstruction on the lower control arm, tighten the lower control arm **rear** mounting bolt nut to 145 N·m (107 ft. lbs.).
6. Attach the stabilizer bar link (1) at each end of the stabilizer bar (2). At each link, install and tighten the nut (3) while holding the stabilizer bar link lower stud stationary. Tighten the nuts to 48 N·m (35 ft. lbs.).

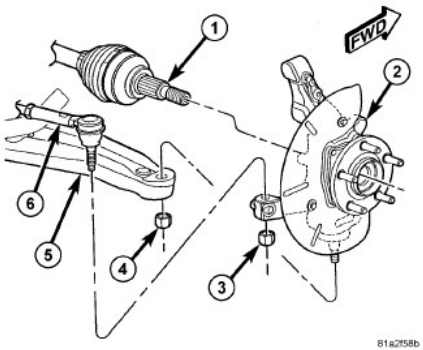


NOTE:

If a new or cleaned lower control arm is being installed, it is important to have a film of general purpose grease around the ball joint mounting hole on the lower control arm to avoid any future corrosion issues. Make sure the grease does not get inside the ball joint mounting hole or on the ball joint stud during installation.

7. Insert the lower ball joint stud into the mounting hole in the lower control arm (5).

8. Install a NEW ball joint stud nut (4). Tighten the nut to 95 N·m (70 ft. lbs.).



9. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten the wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

10. Lower the vehicle.

11. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)

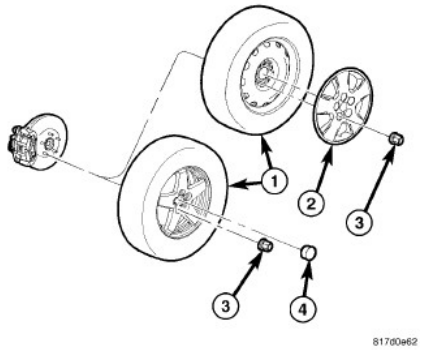
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

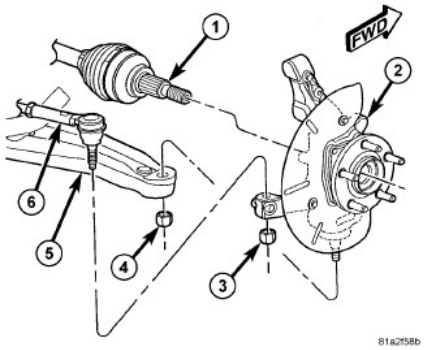
NOTE: Before proceeding, (Refer to 02 - Front Suspension/Front - Warning) .

1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)

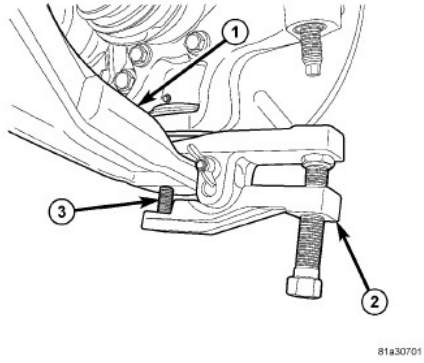
2. Remove the wheel mounting nuts (3), then the tire and wheel assembly (1).



3. Remove the nut (4) attaching the lower ball joint to the lower control arm (5).



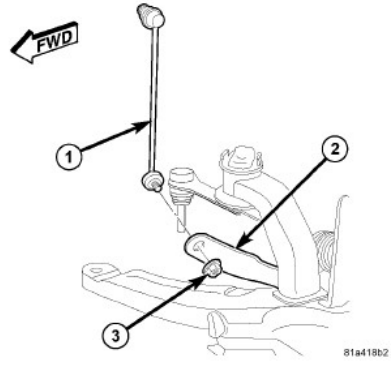
4. Release the lower ball joint (3) from the lower control arm (1) using Remover (2) 9360 . Do not lift the knuckle out of the lower control arm at this time.



CAUTION: **Upon removing the knuckle from the ball joint stud, do not pull outward on the knuckle. Pulling the knuckle outward at this point can separate the inner C/V joint on the half shaft thus damaging it.**

5. At each end of the stabilizer bar, while holding the stabilizer bar link (1) lower stud stationary, remove the nut (3) securing the link to the stabilizer bar (2).

6. Rotate the ends of the stabilizer bar (2) upward away from the lower control arm.



7. Remove the front bolt (1) attaching the lower control arm (3) to the front suspension crossmember.

8. Remove the nut on the rear bolt (2) attaching the lower control arm (3) to the front suspension crossmember. Remove the bolt.

9. Remove the lower control arm (3) from the crossmember.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

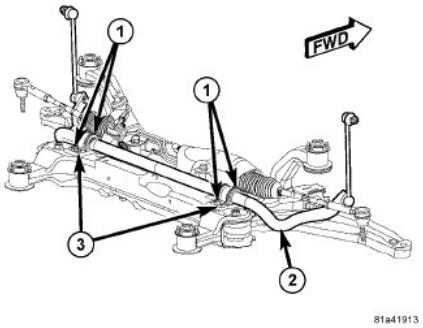
NOTE:

Before stabilizer bar installation, inspect the cushions and links for excessive wear, cracks, damage and distortion. Replace any pieces failing inspection.

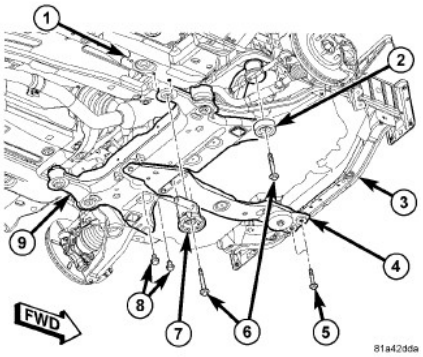
NOTE:

Before installing the stabilizer bar, make sure the bar is not upsidedown. The stabilizer bar must be installed so that when in mounted position, the ends of the bar curve under the steering gear tie rods, up to the links.

1. Install the stabilizer bar, link ends first, from the rear over top of the crossmember. Curve the ends of the bar (2) under the steering gear.
2. Install the two cushions (bushings) on the stabilizer bar utilizing the slit cut into the cushion sides.
3. Install the two stabilizer bushing retainers (3) over the cushions.
4. Install the screws (1) securing the stabilizer bushing retainers (3) to the crossmember. Tighten all four stabilizer bar cushion retainer screws to 60 N·m (44 ft. lbs.).

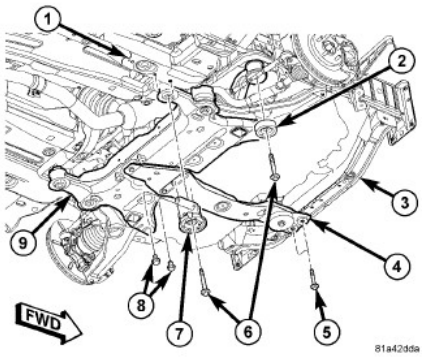


5. Slowly raise the crossmember (9) into mounted position using the transmission jack matching the crossmember to the marked locations on the body made during removal.
6. Position the front crossmember reinforcement brackets (7) (one each side of vehicle) over the crossmember rear mounting bushings and install the mounting screws (8), but do not tighten at this time.



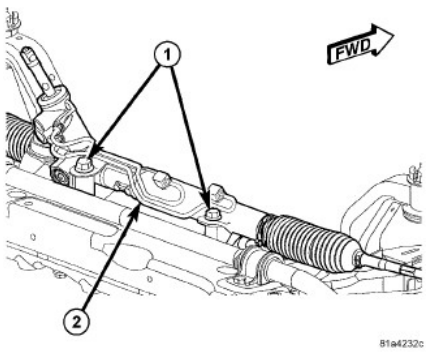
7. Install the four mounting bolts (6) securing the front crossmember (1) to the body. Tighten the crossmember mounting bolts to 135 N·m (100 ft. lbs.).
8. Tighten the crossmember reinforcement bracket mounting screws (8) to 50 N·m (37 ft. lbs.).

9. Remove the transmission jack.

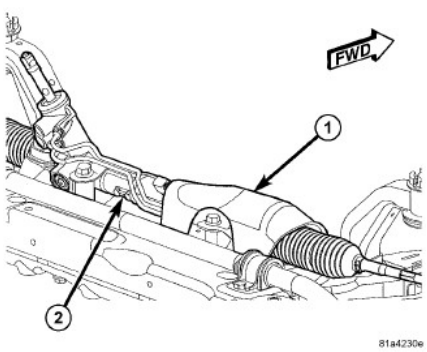


10. Remove the bungee cord or other supporting the steering gear (2).

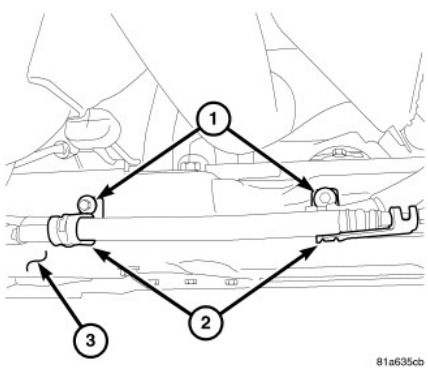
11. Install the two bolts (1) securing the steering gear (2) to the crossmember. Tighten the steering gear mounting bolts to 100 N·m (74 ft. lbs.).



12. Position the heat shield (1) over the steering gear (2). Install the mounting screws and push-pins. Tighten the screws to 6 N·m (53 in. lbs.).

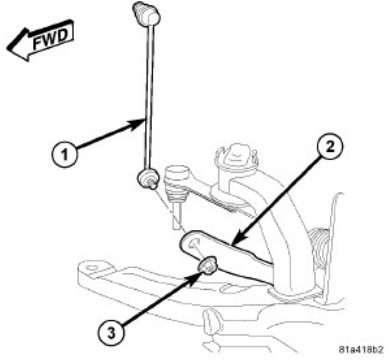


13. Position the power steering hose routing clamps (2) on the crossmember. Install and tighten the screws to 8 N·m (71 in. lbs.).



14. Attach the stabilizer bar link (1) at each end of the stabilizer bar (2). At each link, install and tighten the nut (3) while holding the stabilizer bar link lower stud stationary. Tighten the nuts to 100 N·m (74 ft. lbs.).

15. Install the rear engine mount (Refer to 09 - Engine/Engine Mounting/INSULATOR, Engine Mount - Installation) .
16. Install the front engine mount through-bolt.
17. If equipped, install the engine belly pan.
18. Lower the vehicle.



2014 Dodge JC - DODGE JOURNEY

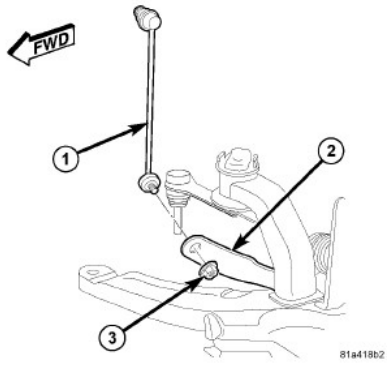
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

REMOVAL

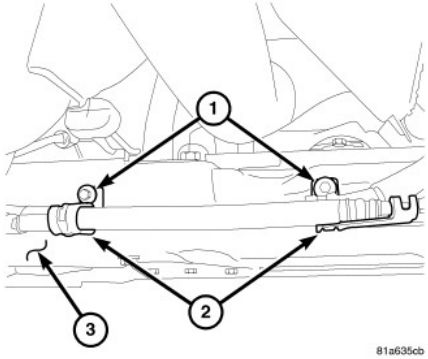
Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: Before proceeding, (Refer to 02 - Front Suspension/Front - Warning) .

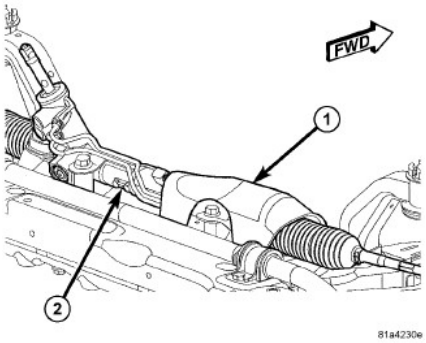
1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)
2. If equipped, remove the engine belly pan.
3. Remove the rear engine mount, (Refer to 09 - Engine/Engine Mounting/INSULATOR, Engine Mount - Removal) .
4. Remove the front engine mount through-bolt.
5. At each end of the stabilizer bar, while holding the stabilizer bar link (1) lower stud stationary, remove the nut (3) securing the link to the stabilizer bar (2).



6. Remove the screws (1) securing the power steering hose routing clamps (2) to the rear of the crossmember.

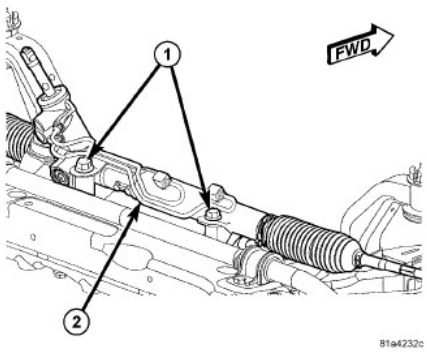


7. Remove the screws and push-pins securing the heat shield (1) over the right side of the steering gear (2).



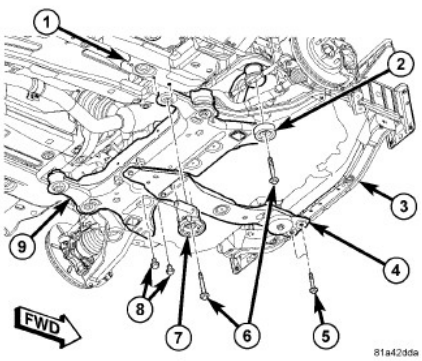
8. Remove the two bolts (1) securing the steering gear (2) to the crossmember.

9. Support the steering gear using a bungee cord or other to keep the steering gear from lowering when the crossmember is lowered.



NOTE:

Before removing the front suspension crossmember from the vehicle, the location of the crossmember must be marked on the body of the vehicle. Do this so the crossmember can be relocated, upon reinstallation, against the body of vehicle in the same location as before removal. If the front suspension crossmember is not reinstalled in exactly the same location as before removal, the preset front wheel alignment settings (caster and camber) may be lost.



10. Mark the location of the front crossmember (9) on the body near each mounting bolt.

11. Support the crossmember (9) with a transmission jack.

12. Remove the four mounting bolts (6) securing the front crossmember (9) to the body.

13. Remove the mounting screws (8) securing the front crossmember reinforcement brackets (7) (one each side of vehicle) to the body (1). Remove the brackets.

14. Slowly lower the crossmember using the jack until there is enough space present to remove the stabilizer bar between the rear of the crossmember and the body. Due to the fact that the fore-and-aft crossmember is still attached, do not lower crossmember any more than necessary to remove the stabilizer bar.

15. Remove the screws (1) securing the stabilizer bushing retainers (3) to the crossmember.

16. Remove the two stabilizer bushing retainers (3).

17. Utilizing the slit cut into the cushions (bushings), remove the two cushions from the stabilizer bar .

18. Remove the stabilizer bar (2) from the vehicle.

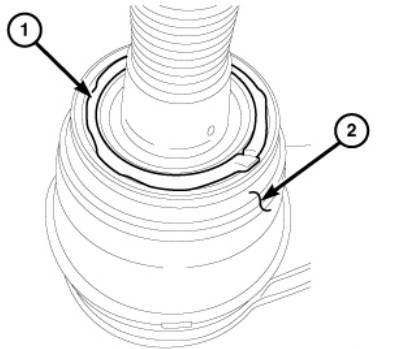
STANDARD PROCEDURE - OUTER TIE ROD END LUBRICATION

NOTE: View is typical.

NOTE: If a new tie rod end is to be installed, make sure the boot (2) is properly lubricated.

Any time the outer tie rod end is disconnected from the knuckle, before assembly, clean all old grease and debris from the boot with a clean cloth and apply outer tie rod grease P/N 68088623AA (1) to the boot (2) as shown.



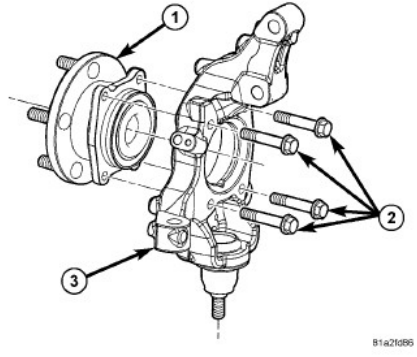
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

The knuckle (3) is a single casting with legs machined for attachment to the front strut assembly on the top and steering linkage on the trailing end. A ball joint is located on the bottom of the knuckle which attaches to the lower control arm. The knuckle also has two machined, drilled legs on the leading end casting to support and align the front disc brake caliper adapter.

The knuckle supports the hub and bearing (1). A shield (not shown in figure) is fastened to the knuckle.



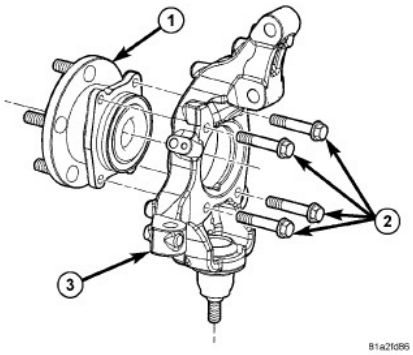
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

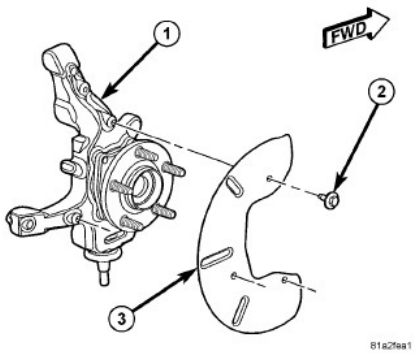
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

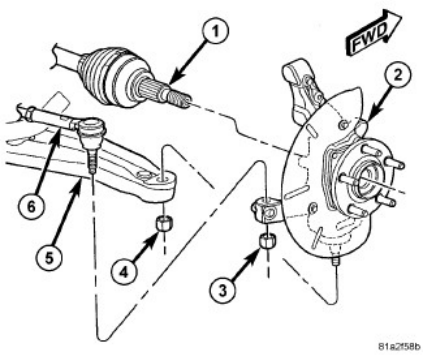
1. If required, install the hub and bearing (1) by sliding it into the knuckle.
2. If installing hub and bearing, install the four bolts (2) fastening the hub and bearing (1) to the knuckle (3). Tighten the four bolts to 48 N·m (35 ft. lbs.).



3. If required, install the shield on the knuckle. Install and tighten the three mounting screws (2) to 10 N·m (89 in. lbs.).



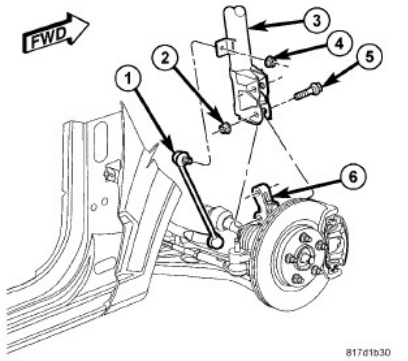
4. Slide the hub and bearing in the knuckle (2) onto the splines of the half shaft outer C/V joint (1).
5. Insert the lower ball joint stud into the mounting hole in the lower control arm.
6. Install a NEW ball joint stud nut (4). Tighten the nut to 95 N·m (70 ft. lbs.).



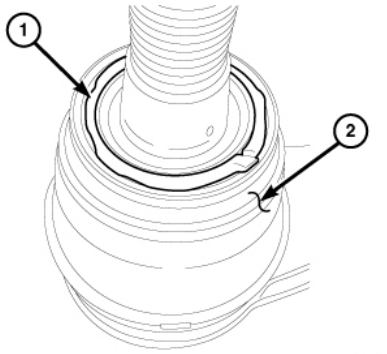
CAUTION: **The strut clevis-to-knuckle bolts (5) are serrated and must not be turned during installation. Install the nuts while holding the bolts stationary in the steering knuckle. Refer to the following step.**

7. Position the lower end of the strut assembly (3) in line with the upper end of the knuckle (6), aligning the mounting holes. Install the two mounting bolts (5).

8. Install the nuts (2) on the two bolts (5). While holding the bolts in place, tighten the nuts to 140 N·m (103 ft. lbs.).



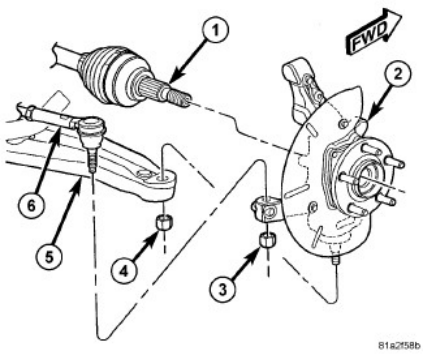
NOTE: If a new tie rod end is to be installed, make sure the boot (2) is properly lubricated.



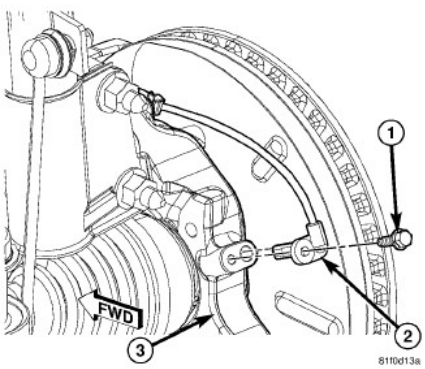
9. Clean all old grease and debris from the boot (2) with a clean cloth.

10. Apply outer tie rod grease P/N 68088623AA (1) to the tie rod end boot (2).

11. Install the outer tie rod (6) ball stud into the hole in the knuckle (2) arm. Start the tie rod end-to-knuckle nut (4) onto the stud. While holding the tie rod end stud with a wrench, tighten the nut with a wrench or crowfoot wrench to 85 N·m (63 ft. lbs.).

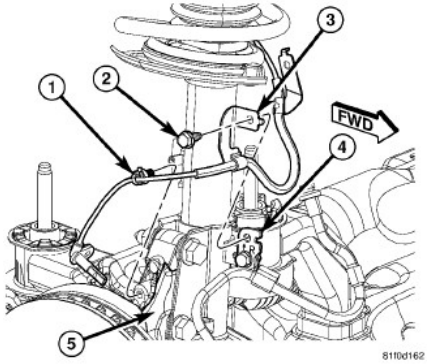


12. Install the wheel speed sensor head (2) into the knuckle (3). Install the mounting screw (1) and tighten it to 12 N·m (106 in. lbs.).

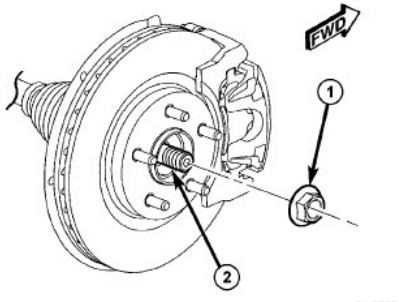


13. Install the routing clip (1) securing the wheel speed sensor cable to the knuckle (5).

14. Install the brake rotor, disc brake caliper and adapter. (Refer to 05 - Brakes/Hydraulic /Mechanical/ROTOR, Brake - Installation)



NOTE: Always install a new hub nut. The original hub nut is one-time use only and should be discarded when removed.



15. Clean all foreign matter from the threads of the half shaft outer C/V joint.

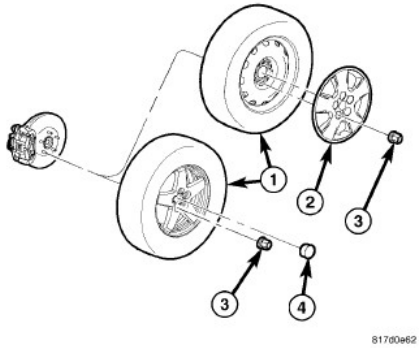
16. Install the hub nut (1) on the end of the half shaft (2) and snug it.

17. While a helper applies the brakes to keep the hub from rotating, tighten the hub nut (3) to 132 N·m (97 ft. lbs.).

18. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

19. Lower the vehicle.

20. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)



2014 Dodge JC - DODGE JOURNEY

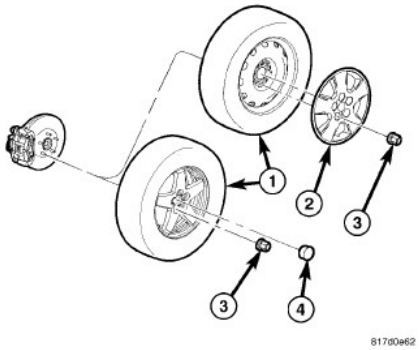
Fuel Delivery: | **Fuel:**

REMOVAL

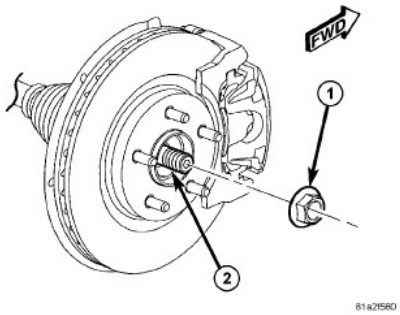
Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

NOTE: Before proceeding, review all Warnings and Cautions. (Refer to 02 - Front Suspension/Front - Warning)

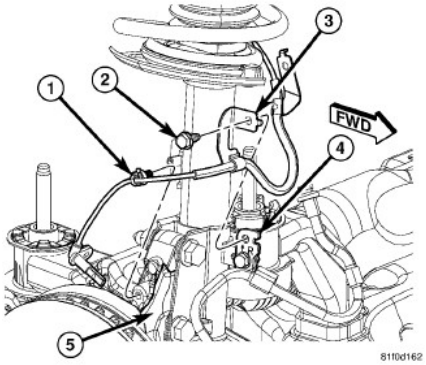
1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)
2. Remove the wheel mounting nuts (3), then the tire and wheel assembly (1).



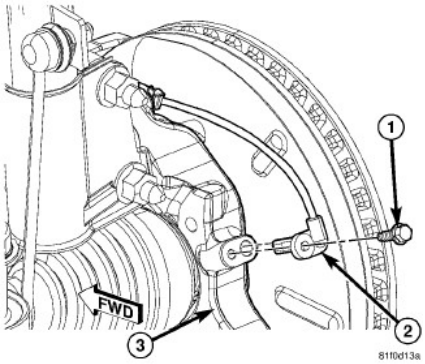
3. While a helper applies the brakes to keep the hub from rotating, remove the hub nut (1) from the axle half shaft (2).
4. Access and remove the front brake rotor. (Refer to 05 - Brakes/Hydraulic/Mechanical /ROTOR, Brake - Removal)



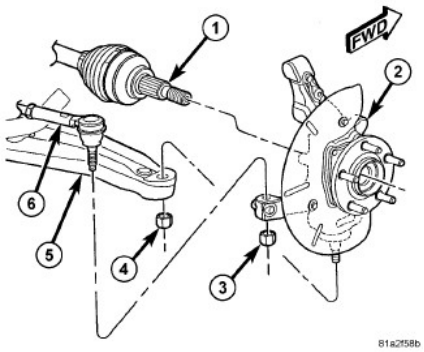
5. Remove the routing clip (1) securing wheel speed sensor cable to the knuckle (5).



6. Remove the screw (1) fastening the wheel speed sensor head (2) to the knuckle (3). Pull the sensor head out of the knuckle.

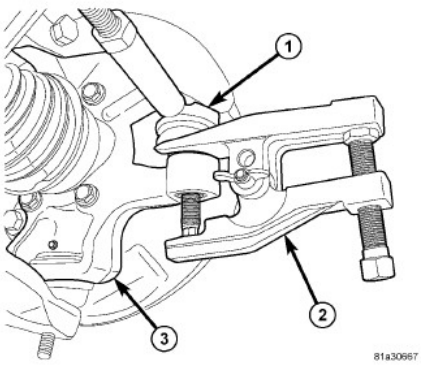


7. Remove the nut (3) attaching the outer tie rod (6) to the knuckle (2). To do this it might be necessary to hold the tie rod end stud with a wrench while loosening and removing the nut with a standard wrench or crowfoot wrench.

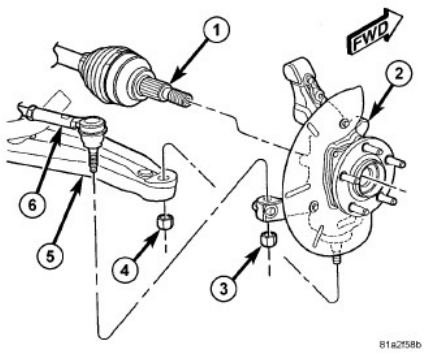


8. Release the outer tie rod end (1) from the knuckle (3) using Remover (2), Special Tool 9360 .

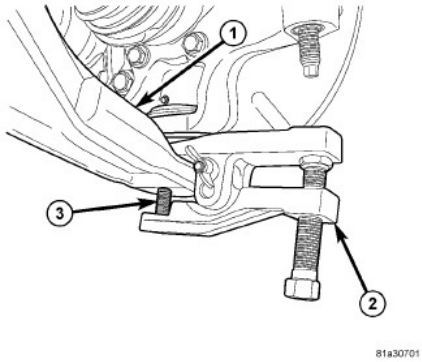
9. Remove the outer tie rod from the knuckle.



10. Remove the nut (4) attaching the lower ball joint to the lower control arm (5).



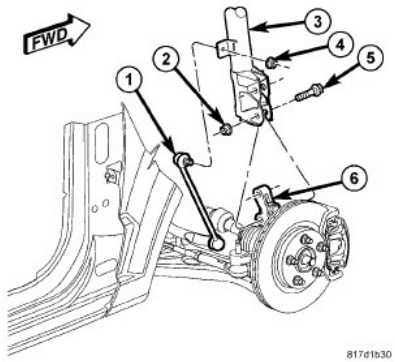
11. Release the lower ball joint (3) from the lower control arm (1) using Remover (2), Special Tool 9360 . Do not lift the knuckle out of the lower control arm at this time.



CAUTION: **The strut assembly-to-knuckle attaching bolts (5) are serrated and must not be turned during removal. Proper removal is required. Refer to the following steps for the correct method.**

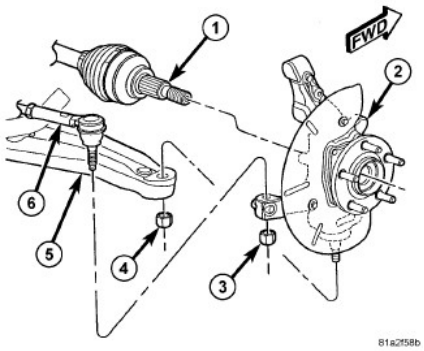
12. While holding the bolt heads stationary, remove the two nuts (2) from the bolts (5) attaching the strut (3) to the knuckle (6).

13. Remove the two bolts (5) attaching the strut (3) to the knuckle (6) using a pin punch.

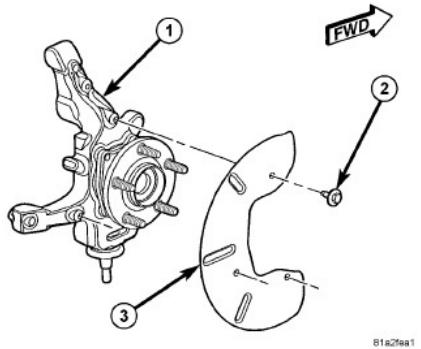


NOTE: Do not allow the half shaft (1) to hang by the inner C/V joint; it must be supported to keep the joint from separating during this operation.

14. Pull the knuckle (2) off the half shaft (1) outer C/V joint splines and remove the knuckle from the vehicle.



15. If required, remove the three screws (2) fastening the shield (3) to the knuckle (1). Remove the shield.



16. If required, remove the four bolts (2) fastening the hub and bearing (1) to the knuckle (3).

17. If required, slide the hub and bearing (1) out of the knuckle.

WARNING

WARNING:

Chrysler LLC does not manufacture any vehicles or replacement parts that contain asbestos. Aftermarket products may or may not contain asbestos. Refer to aftermarket product packaging for product information.

Whether the product contains asbestos or not, dust and dirt can accumulate on brake parts during normal use. Follow practices prescribed by appropriate regulations for the handling, processing and disposing of dust and debris.

WARNING:

Do not remove the strut rod nut while strut assembly is installed in vehicle, or before the coil spring is compressed with a compression tool. The spring is held under high pressure.

CAUTION:

At no time when servicing a vehicle can a sheet metal screw, bolt, or other metal fastener be installed in the shock tower to take the place of an original plastic clip. It may come into contact with the strut or coil spring.

CAUTION:

Wheel bearing damage will result if after loosening the axle hub nut, the vehicle is rolled on the ground or the weight of the vehicle is allowed to be supported by the tires for any length of time.

STANDARD PROCEDURE - LUBRICATION

There are no serviceable lubrication points on the front or rear suspension. The ball joints and tie rod ends are sealed for life and require no maintenance.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

CURB HEIGHT MEASUREMENT

The wheel alignment is to be checked and all alignment adjustments made with the vehicle at its required curb height specification.

Vehicle height is to be checked with the vehicle on a flat, level surface, preferably a vehicle alignment rack. The tires are to be inflated to the recommended pressure. All tires are to be the same size as standard equipment. **Vehicle height is checked with the fuel tank full of fuel, and no passenger or luggage compartment load.**

Vehicle height is not adjustable. If the measurement is not within specifications, inspect the vehicle for bent or weak suspension components. Compare the parts tag on the suspect coil spring(s) to the parts book and the vehicle sales code, checking for a match. Once removed from the vehicle, compare the coil spring height to a correct new or known good coil spring. The heights should vary if the suspect spring is weak.

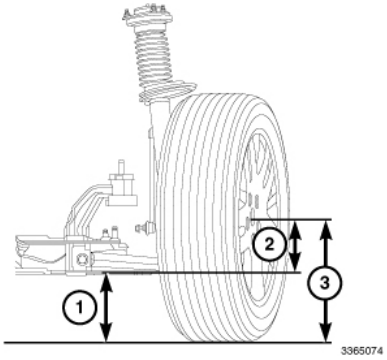
NOTE: Prior to reading the curb height measurement, the front and rear of the vehicle must be jounced to settle the suspension. Induce jounce by pushing down on the center of the bumper (fascia), using care not to damage the vehicle, moving the vehicle up and down, gradually increasing the suspension travel with each stroke. Release the bumper at the bottom of each stroke, repeating this action several times. Perform this to both front and rear suspensions an equal amount of times.

Measure curb height as follows:

1. Jounce the vehicle. Refer to above note.

NOTE: On some vehicles it may be necessary to remove an engine belly pan in order to gain access to the lower control arm pivot bolt.

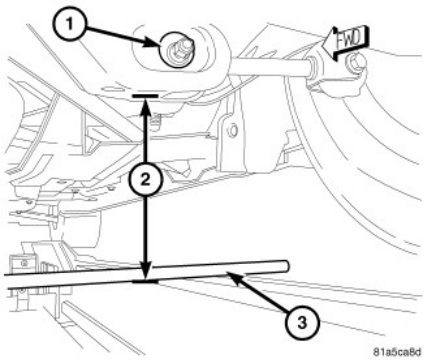
2. FRONT – On each side of the vehicle, measure the distance (1) from the flat surface on the crossmember to the floor or alignment rack/lift runway surface. It may be necessary to measure to the bottom of a straight edge placed from lift runway to runway to get an accurate measurement.



3. FRONT – Measure and record the distance (3) from the center of the spindle to the same surface or straight edge used to measure from the flat surface on the crossmember.

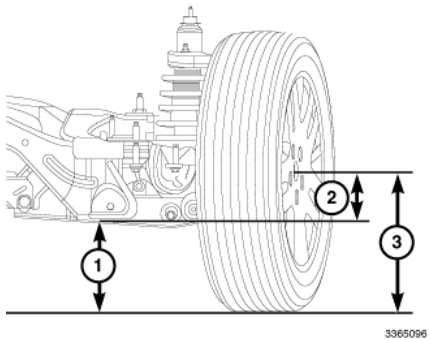
4. Subtract the flat surface area on the crossmember (1) from the spindle height (3) to obtain the curb height value (2). Compare the curb height value (2) to specifications listed in the following CURB HEIGHT SPECIFICATIONS chart. **Maximum left-to-right differential is not to exceed 12 mm (0.5 in.).**

5. REAR – On each side of the vehicle, measure and record the distance (2) from the flat surface below the rear toe adjustment cam bolt (1) to the floor or alignment rack/lift runway surface. It may be necessary to measure to the bottom of a straight edge (3), placed from lift runway to runway, to get an accurate measurement.



6. REAR – On each side of the vehicle, measure and record the distance (3) from the center of the rear spindle to the same surface that was used to measure to below the bolt in the previous step.

7. REAR – Subtract the mounting bolt height (1) (found in **Step #5**) from the spindle height (3) to obtain the curb height value (2). Compare the curb height value (2) to specifications listed in the following CURB HEIGHT SPECIFICATIONS chart.
Maximum left-to-right differential is not to exceed 12 mm (0.5 in.).



8. If curb height is found to be out of specification and there is no sign of excessive body damage, curb height can be changed by replacing the applicable spring with a spring offering a different check load. (Refer to 02 - Front Suspension/Front/STRUT, Suspension - Removal)

CURB HEIGHT SPECIFICATIONS

VEHICLE	FRONT	REAR
ALL WHEEL DRIVE	134.4 mm ± 12 mm 5.29 in. ± 0.47 in.	105.5 mm ± 12 mm 4.15 in. ± 0.47 in.
FRONT WHEEL DRIVE	140.4 mm ± 12 mm 5.53 in. ± 0.47 in.	112.5 mm ± 12 mm 4.43 in. ± 0.47 in.

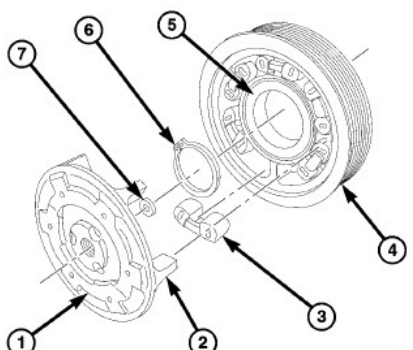
HUB AND PULLEY - VARIABLE DISPLACEMENT A/C COMPRESSOR

NOTE: Typical clutchless A/C compressor pulley and drive hub shown.

The non-servicable hub and pulley assembly for the Denso 6SEU16 and the Valeo variable displacement A/C compressors provides the means to drive the compressor using the engine accessory drive belt. The hub and pulley assembly consists of an aluminum drive hub (1) with composite tabs (2) that are positioned between rubber dampeners (3), which are located inside of a composite pulley (4).

The A/C pulley has a bearing (5) which is retained to the front of the A/C compressor with a snap ring (6). The drive hub and shim (7) are retained to the compressor shaft by use of left handed threads.



2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

HUB AND PULLEY INSPECTION - VARIABLE DISPLACEMENT A/C COMPRESSOR

NOTE: The compressor drive hub and the pulley and bearing assembly can not be serviced separately from the A/C compressor. In the event of drive hub or pulley and bearing assembly damage or failure, the A/C compressor, drive hub and pulley and bearing must be replaced as an assembly.

NOTE: Typical clutchless compressor drive hub and pulley and bearing assembly shown.

The bridges (1) located on the non-servicable compressor hub (2) are designed to break away in the event of compressor seizure. Examine the bridges for separation or cracks (3). Damage to the bridges are an indication of excessive compressor torque, which is most likely caused by compressor failure.

Check the non-servicable pulley bearing (4) for roughness or excessive noise. Check the pulley dampeners (5) for excessive play which can be caused by deterioration or damage. Inspect the belt surfaces of the non-servicable pulley (4) for wear. If the pulley surfaces are oily, inspect the shaft and nose area of the A/C compressor for refrigerant oil. If refrigerant oil is found, the compressor shaft seal is leaking and the A/C compressor must be replaced.

Replace the A/C compressor if wear or damage is found to the drive hub or pulley and bearing assembly (Refer to 24 - Heating and Air Conditioning/Plumbing/COMPRESSOR, A/C - Removal) .

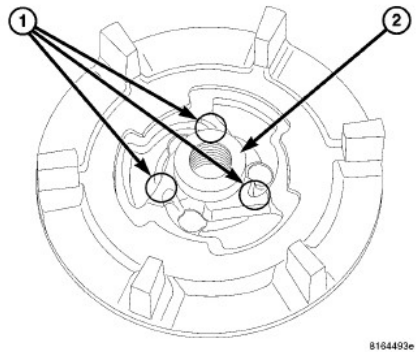
HUB AND PULLEY - VARIABLE DISPLACEMENT A/C COMPRESSOR

NOTE: Typical clutchless compressor pulley drive hub shown.



The design of the Denso 6SEU16 and Valeo variable displacement A/C compressors does not require the use of an electromagnetic clutch, as the compressor is controlled by an integral control valve that allows refrigerant to bypass within the compressor (Refer to 24 - Heating and Air Conditioning/Plumbing /COMPRESSOR, A/C - Description) .

The bridges (1) located on the compressor drive hub (2) are designed to break away in the event of compressor seizure. This action prevents damage to the serpentine accessory drive belt (Refer to 24 - Heating and Air Conditioning/Plumbing/COMPRESSOR, A/C - Inspection) .

NOTE: The compressor drive hub and the pulley and bearing assembly can not be serviced separately from the A/C compressor. In the event of drive hub or pulley and bearing assembly damage or failure, the A/C compressor, drive hub and pulley and bearing must be replaced as an assembly.

The compressor drive hub and the pulley and bearing assembly can not be serviced separately from the A/C compressors. The A/C compressors must be replaced if the drive hub or pulley and bearing assembly is worn or damaged.

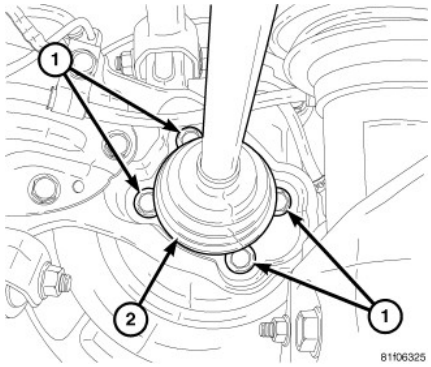
ALL-WHEEL-DRIVE

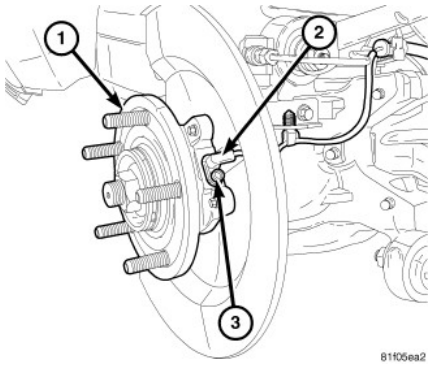
Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

1. With the brake shield in place on the knuckle, slide the hub and bearing over the axle half shaft and position it on the knuckle.
2. Install the four bolts (1) securing the hub and bearing to the knuckle. Tighten the bolts to 61 N·m (45 ft. lbs.).

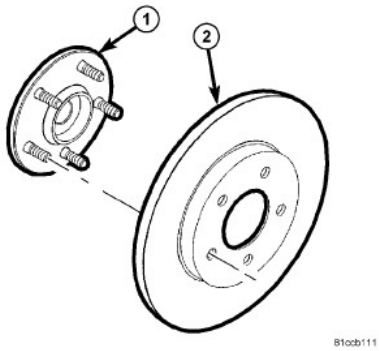


CAUTION: **Ensure that sensor mounting surface on bearing is clean before sensor installation.**

3. Pass the wheel speed sensor head (2) through the hole in the brake shield, then push it into the mounting hole in hub and bearing (1) and align the mounting screw hole.
4. Install a NEW mounting screw (2). Tighten the mounting screw to 6 N·m (55 in. lbs.).



5. Clean the rotor mounting face of the hub and bearing (1) to remove any dirt or corrosion.
6. Install the brake rotor (2) over the hub and bearing (1).



CAUTION: **If the brake rotor or brake pads are being replaced, the rear caliper piston must be seated (bottomed) to compensate for the new brake rotor or lining. Because the parking brake self-adjuster mechanism is attached to the piston, a special seating method is required. The only acceptable method is by rotating the piston back into the bore using Retractor, Special Tool , as described below. Any other seating method will damage the self-adjuster mechanism.**

7. If necessary, seat (bottom) the caliper piston in the bore as follows:

   a. Assemble a 3/8 in. drive ratchet handle and an extension (3).

   b. Insert the extension through Special Tool 8807-1 (2).

   c. Place Special Tool 8807-2 (1) on the end of the extension.

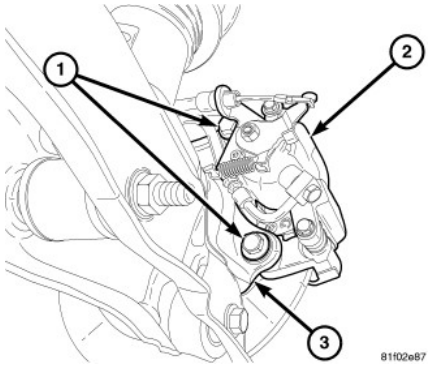
   d. Insert lugs on Special Tool 8807-2 into notches in face of caliper piston (5).

   e. Thread the screw drive on 8807-1 down until it contacts the top of 8807-2 which is against the caliper piston. **Do not over tighten the screw-drive. Damage to the piston can occur.**

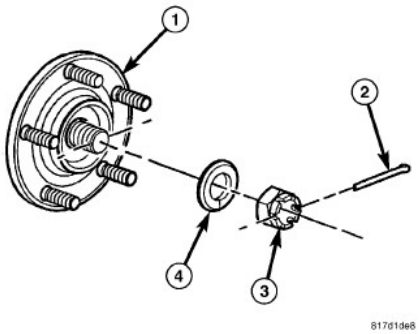
   f. Turn 8807-2 with the ratchet, rotating the piston in a **clockwise** direction until fully seated (bottomed) in the bore. **It may be necessary to turn** 8807-1 **with** 8807-2 **to start the process of piston retraction.**

8. Install the disc brake caliper and adapter bracket (2) over the knuckle and rotor as an assembly.

9. Install the two bolts (1) securing the disc brake caliper and adapter bracket (2) to the knuckle. Tighten the mounting bolts to 100 N·m (74 ft. lbs.).



NOTE: Always install a new hub nut. The original hub nut is one-time use only and should be discarded when removed.



10. Clean all foreign matter from the threads of the half shaft outer C/V joint.

11. Install the washer (4) and hub nut (3) on the end of the half shaft and snug it.

12. While a helper applies the brakes to keep the hub (1) from rotating, tighten the hub nut (3) to 245 N·m (181 ft. lbs.).

13. Insert the cotter pin (2) through the notches in the nut and the hole in half shaft. If the notches in the nut do not line up with the hole in the half shaft, continue to tighten the nut until they do. **Do not loosen the nut.**

14. Wrap the cotter pin (2) ends tightly around the lock nut.

15. Install tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

16. Lower the vehicle.

17. Pump the brake pedal several times to ensure the vehicle has a firm brake pedal before moving it. Check the brake fluid level.

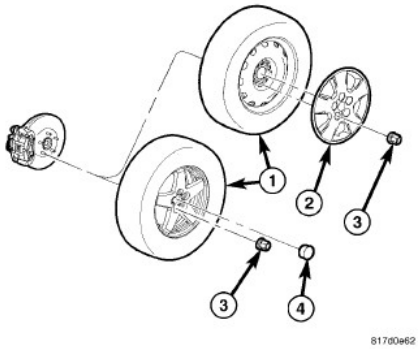
ALL-WHEEL-DRIVE

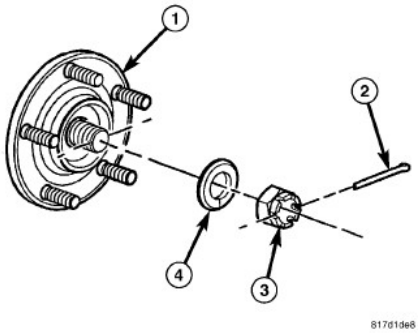
Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE: Before proceeding, (Refer to 17 - Rear Suspension - Warning) .

1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)
2. Remove the wheel mounting nuts (3), then the tire and wheel assembly (1).



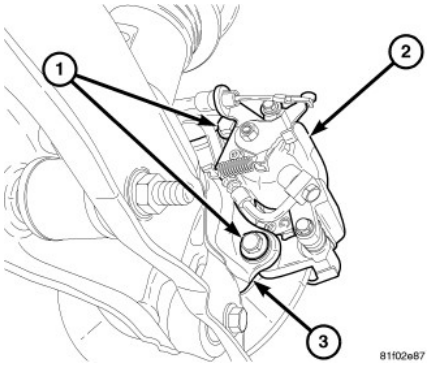
3. Remove the cotter pin (2) from the hub nut (3) on the end of the axle half shaft.
4. While a helper applies the brakes to keep the hub (1) from rotating, remove the hub nut (3) and washer (4) from the axle half shaft.
5. Tap the end of the half shaft inward, loosening it from the hub and bearing. This will also allow more room to access the hub and bearing mounting bolts in a later step.



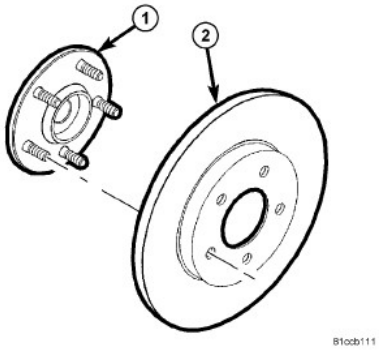
NOTE: In some cases, it may be necessary to retract the caliper piston in its bore a small amount in order to provide sufficient clearance between the pads and the rotor to easily remove the caliper from the knuckle. This can usually be accomplished before removal by grasping the inboard side of the caliper and pulling outward working with the guide pins, thus retracting the piston. Never push on the piston directly as it may get damaged.

6. Remove two bolts (1) securing the disc brake caliper and adapter bracket (2) to the knuckle (3).

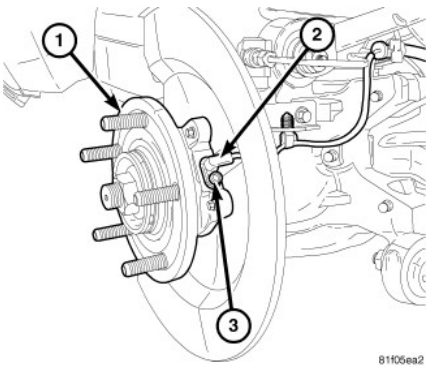
7. Remove the disc brake caliper and adapter bracket (2) as an assembly from the knuckle (3) and rotor. Hang the assembly out of the way using wire or a bungee cord. Use care not to overextend the brake hose when doing this.



8. Remove any retaining clips, then slide the brake rotor (2) off the hub and bearing (1).



CAUTION: **Prior to removal, clean area around sensor head to help prevent contaminants from entering bearing when sensor head is removed.**



9. Remove the screw (3) fastening the speed sensor head (2) to the hub and bearing (1).

10. Remove the wheel speed sensor head (2) from the hub and bearing (1), then pass it through the brake shield.

11. Remove the four bolts (1) securing the hub and bearing to the knuckle.

12. Remove the hub and bearing from the knuckle and half shaft (2).

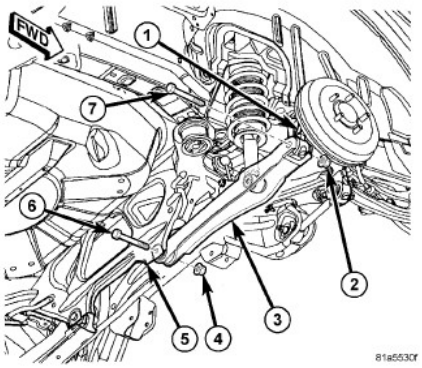
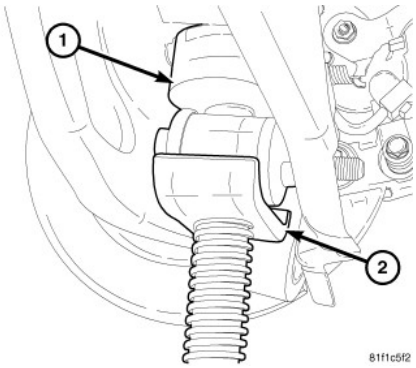
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

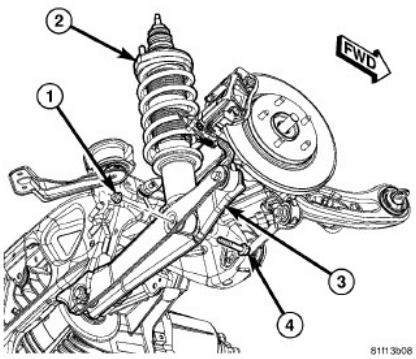
1. Position the lower control arm (3) and install the bolt (6) and nut (4) securing the lower control arm to the crossmember (5). Do not tighten at this time.
2. Install the bolt (7) and nut (2) securing the lower control arm (3) to the knuckle (1). Do not tighten at this time.



3. If equipped with load-leveling shocks, place a jack (2) against the lower shock eye and support the lower end of the shock assembly (1). Lift the shock assembly using the jack until the hole in the lower shock eye lines up with that in the lower control arm.



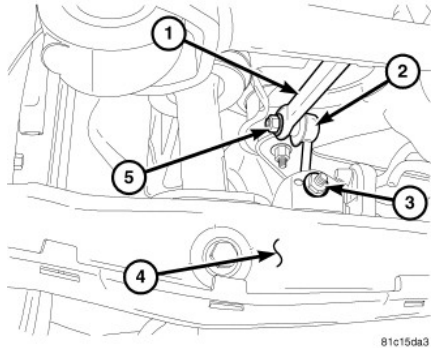
4. Install the mounting bolt (4) and nut (1) fastening the shock assembly (2) to the lower control arm (3). Do not tighten at this time.



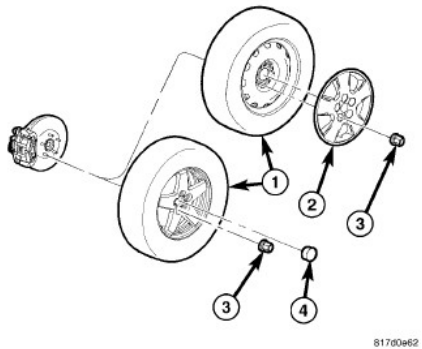
NOTE:

When attaching a stabilizer bar link to the lower control arm it is important that the lower mounting stud be positioned properly. The lower mounting stud on the right side link needs to point toward the front of the vehicle when inserted through the lower control arm mounting flange. The left side link lower stud needs to point toward the rear of the vehicle. Otherwise the suspension geometry will not function properly.

CAUTION: **Before installing the nut in the following step, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**



5. If equipped, attach the stabilizer bar link (2) to the lower control arm (4). Install the nut (3) and while holding the stabilizer bar link lower stud stationary, tighten the nut (3) to 100 N·m (74 ft. lbs.).



6. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten the wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).
7. Lower the vehicle.
8. Position the vehicle on an alignment rack/drive-on lift. Raise the vehicle as necessary to access mounting bolts and nuts.
9. Tighten the lower control arm mounting bolt nut at the crossmember to 105 N·m (77 ft. lbs.).
10. Tighten the lower control arm mounting bolt nut at the knuckle to 105 N·m (77 ft. lbs.).
11. Tighten the shock assembly lower mounting bolt nut to 99 N·m (73 ft. lbs.).
12. Perform wheel alignment as necessary (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure) .

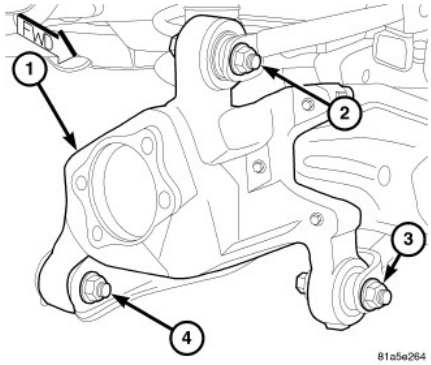
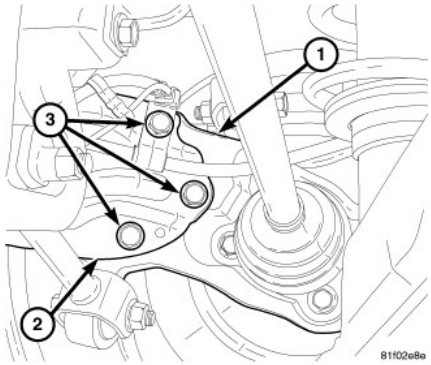
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

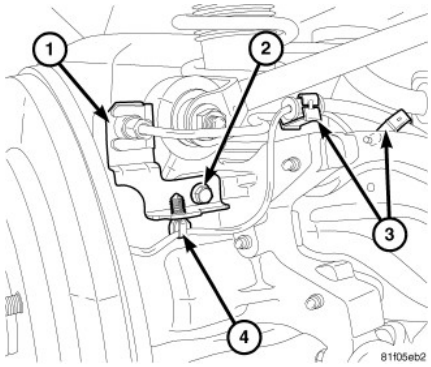


1. Position the knuckle (1) on the upper and lower control arm, and the toe link.
2. Install the bolt and nut (2) securing the upper control arm to the knuckle. Do not tighten the mounting bolt nut at this time.
3. Install the bolt and nut (4) securing the lower control arm to the knuckle. Do not tighten the mounting bolt nut at this time.
4. Install the bolt and nut (3) securing the toe link to the knuckle. Do not tighten the mounting bolt nut at this time.

CAUTION: **Before installing the bolts in the following step, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**



5. Install the three bolts (3) securing the trailing link (2) to the knuckle (1). Be sure to include the parking brake cable routing clamp when installing the top mounting bolt. Tighten the mounting bolts to 70 N·m (52 ft. lbs.).
6. Install the hub and bearing, then the brake rotor and caliper (Refer to 17 - Rear Suspension/HUB AND BEARING - Installation) .



7. Position the brake tube routing bracket (1) at the knuckle and install the mounting screw. Tighten the screw to 15 N·m (11 ft. lbs.).
8. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten the wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).
9. Lower the vehicle.
10. Position the vehicle on an alignment rack/drive-on lift. Raise the vehicle as necessary to access yet to be tightened mounting bolts and nuts.

11. Tighten the upper control arm bolt nut at the knuckle to 105 N·m (77 ft. lbs.).
12. Tighten the lower control arm bolt nut at the knuckle to 105 N·m (77 ft. lbs.).
13. Tighten the toe link mounting bolt nut at the knuckle to 105 N·m (77 ft. lbs.).
14. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)

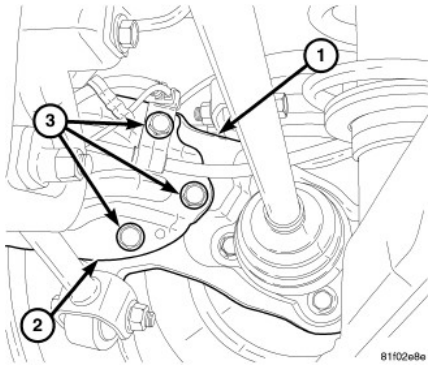
INSTALLATION

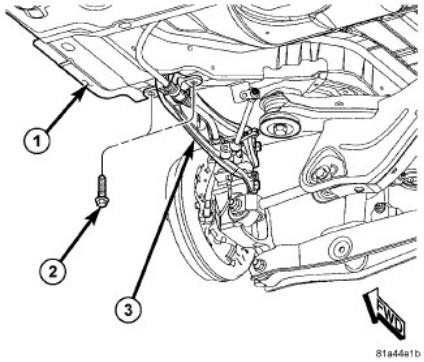
Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **Before installing the bolts in the following step, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**

1. Position the trailing link (2) and install the three bolts (3) securing the trailing link to the knuckle (1). Be sure to include the parking brake cable routing clamp when installing the top mounting bolt. Tighten the mounting bolts to 80 N·m (59 ft. lbs.).

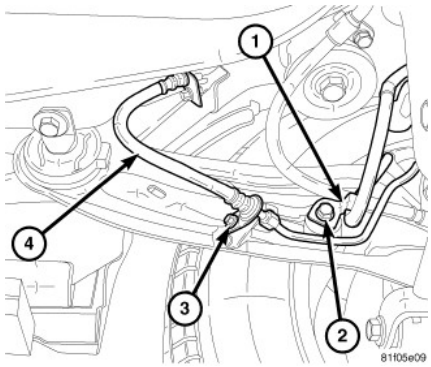


2. Position the forward end of the trailing link (3) on the body (1) and install the two mounting bolts (2). Do not tighten the bolts at this time.



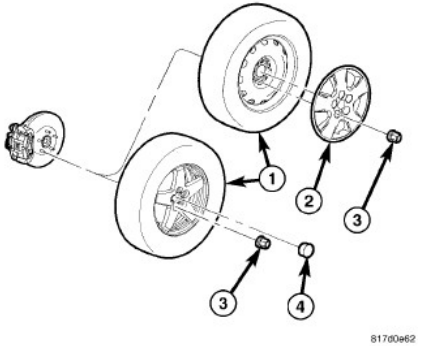
3. Position the brake flex hose and tube bracket (4) on the trailing link and install the mounting screw (3). Tighten the screw to 23 N·m (17 ft. lbs.).

4. Attach the wheel speed sensor routing clip (1) to the trailing link using the mounting screw (2).



5. Install tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

6. Lower the vehicle.



7. Position the vehicle on an alignment rack/drive-on lift. Raise the vehicle as necessary to access yet to be tightened mounting bolts.

8. Tighten the two mounting bolts fastening the leading end of the trailing link (3) to the body (1) to 110 N·m (81 ft. lbs.).

9. Perform wheel alignment as necessary (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure) .

ASSEMBLY

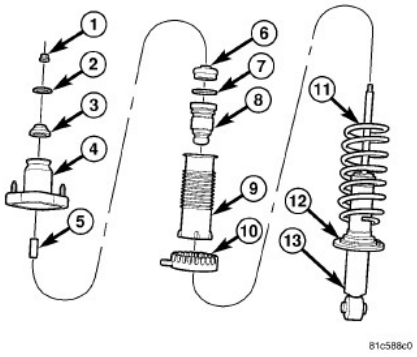
Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **Do not use any type of pliers on the chrome machined surface of shock/strut rod to assist in the disassembly/assembly of shocks or struts. Use only tools designed to hold the shock/strut rod stationary when servicing shock or strut components.**

NOTE: If the coil spring has been removed from the spring compressor, proceed with the next step, otherwise, proceed with Step #3.

NOTE: To determine the flat coil end of the coil spring for the following step, attempt to stand the coil spring on end on a flat, level surface. If the coil spring stands on end, the end on the flat surface is the flat coil end. If the coil spring falls over, the end on the flat surface is not the flat coil end. Stand the coil spring on the opposite end to verify.

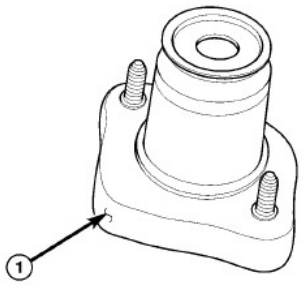
1. Place the coil spring flat coil end downward (see above note) in the spring compressor following the manufacturer's instructions.
2. Slowly compress the coil spring until enough room is available for shock assembly reassembly.



3. Assemble the bushings (3, 6) and sleeve (5) through the upper mounting bracket (4).

NOTE:

When installing the upper spring isolator on the upper mounting bracket in the following step, make sure the tab on the isolator is positioned toward the forward mounting stud on the mounting bracket. To determine the forward mounting stud on the mounting bracket, position the angular formed side (as viewed from above; opposite side of bracket is rounded) of the mounting bracket flange (1) toward you with the mounting studs pointing upwards. The stud to the left would be the forward mounting stud for a left rear shock assembly. The stud to the right would be the forward mounting stud for a right rear shock assembly.

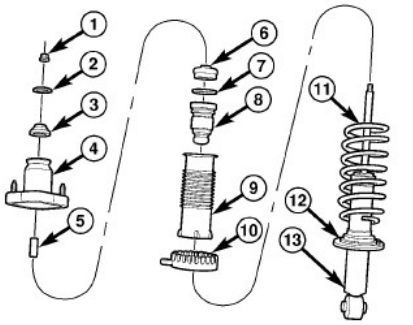


81f837fc

4. If not already together, install the upper spring isolator (10) on the upper mounting bracket (4). Make sure the tab on the isolator is positioned toward the forward mounting stud on the mounting bracket (See above note).

5. Install the upper mounting bracket (4) on top of the coil spring (11) matching the step in the isolator to the end of the coil.

6. Install the lower spring isolator (12) on the spring seat of the shock absorber (13).

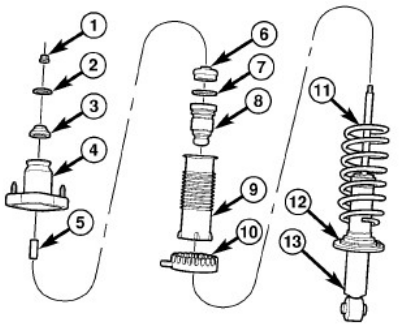


81c588c0

7. Slide the dust shield (9), jounce bumper (8) and washer (7) onto the shock rod.

8. Install the shock absorber (13) up through the bottom of the coil spring (11) and upper mounting bracket until the lower spring seat contacts the lower end of the coil spring.

9. While holding the shock absorber in position, install the washer (2) and nut (1) on the end of the shock rod.

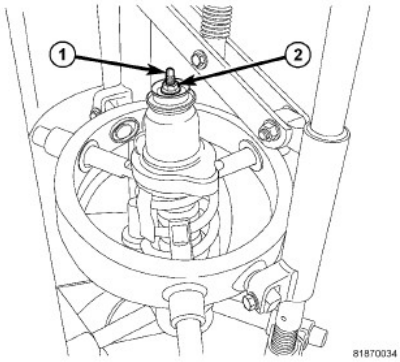


81c588c0

CAUTION:

Never use impact or high speed tools to remove the shock rod nut. Damage to the shock internal bearings can occur.

10. Install Snap-On® Shock Absorber Socket A139, or equivalent, on the end of the shock rod (1). While holding the shock rod from turning, tighten the nut (2) using a crows foot wrench and a torque wrench. Tighten the shock rod nut to 41 N·m (30 ft. lbs.).



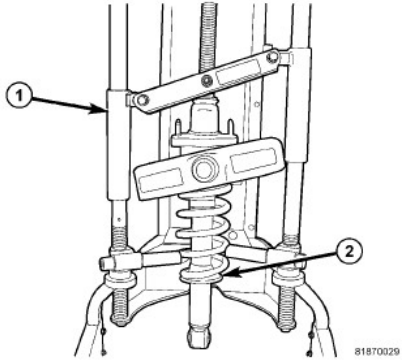
81870034

11. Turn the upper mounting bracket or shock absorber as necessary until the mounting studs on the mounting bracket line up with the lower mounting bolt eyelet at the bottom of the shock absorber.

12. Slowly release the tension from the coil spring by backing off the compressor (1) drive completely.

13. Remove the shock assembly from the spring compressor.

14. Install the shock assembly on the vehicle. (Refer to 17 - Rear Suspension/SHOCK ABSORBER, Suspension - Installation)



2014 Dodge JC - DODGE JOURNEY

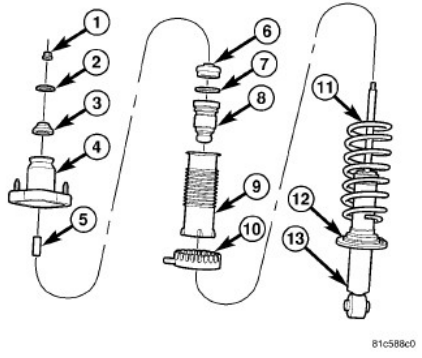
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

A coil-over shock absorber assembly supports each side of the vehicle. The bottom of the shock assembly mounts to the lower control arm. The top of the shock assembly mounts to the body.

The shock assembly includes the following major components:

- Upper bushing (3)
- Upper mounting bracket (4)
- Sleeve (5)
- Lower bushing (6)
- Jounce bumper (8)
- Dust shield (9)
- Upper spring isolator (10)
- Coil spring (11)
- Lower spring isolator (12)
- Shock absorber (damper) (13)



Each component is serviced by removing the shock assembly from the vehicle and disassembling it.

Coil springs are rated separately for each corner or side of the vehicle depending on optional equipment and type of vehicle service. If a coil spring requires replacement, be sure that it is replaced with a spring meeting the correct load rating for the vehicle and its specific options.

DISASSEMBLY

Labor Operations: Click to display a list of Labor Operations associated with this procedure

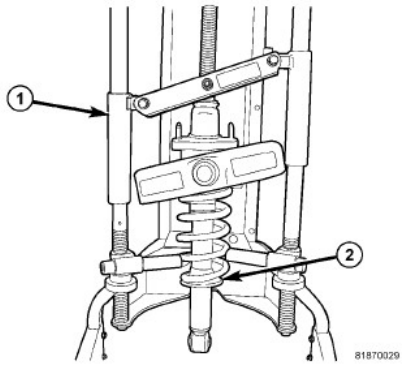
CAUTION: **Do not use any type of pliers on the chrome machined surface of shock/strut rod to assist in the disassembly/assembly of shocks or struts. Use only tools designed to hold the shock/strut rod stationary when servicing shock or strut components.**

NOTE: The shock assembly must be removed from the vehicle for it to be disassembled and assembled. (Refer to 17 - Rear Suspension/SHOCK ABSORBER, Suspension - Removal)

For the disassembly and assembly of the shock assembly, use Strut Spring Compressor, teamPSE tool 223-7400, or the equivalent, to compress the coil spring. Follow the manufacturer's instructions closely.

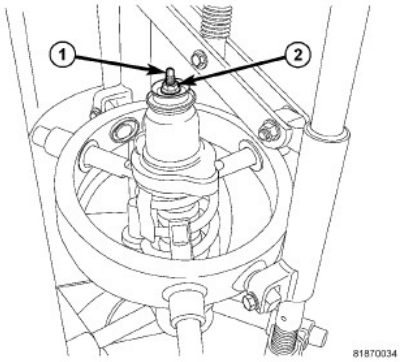
WARNING: **Do not remove the shock rod nut before the coil spring is properly compressed. The coil spring is held under pressure. The coil spring must be compressed, removing spring tension from the upper mounting bracket, before the shock rod nut is removed.**

1. If both shocks are being serviced at the same time, mark both the coil spring and shock assembly according to which side of the vehicle the shock is being removed from.
2. Position the shock assembly (2) in the strut spring compressor (1) following the manufacturer's instructions and set the lower and upper hooks of the compressor on the coil spring.
3. Compress the coil spring until all spring tension is removed from the upper mounting bracket and bushings.



CAUTION: **Never use impact or high speed tools to remove the shock rod nut. Damage to the shock internal bearings can occur.**

4. Once the spring is sufficiently compressed, install Snap-On® Shock Absorber Socket A139, or equivalent, on the end of the shock rod (1). While holding the shock rod from turning, remove the nut (2) using a wrench. Remove the washer below the nut.



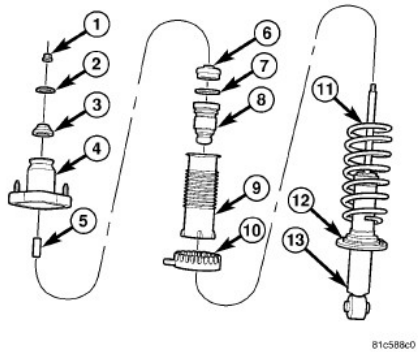
5. Remove the shock absorber (13) out through the bottom of the coil spring (11). The washer (7), jounce bumper (8), dust shield (9) and lower spring isolator (12) will come out with the shock.

6. Slide the washer (7), jounce bumper (8), and dust shield (9) from the shock rod.

7. Remove the lower spring isolator (12) from the shock spring seat.

8. Remove the upper mounting bracket (4), bushings (3, 6), sleeve (5) and upper spring isolator (10) from the top of the spring.

9. Remove the bushings (3, 6), sleeve (5) and upper spring isolator (10) from the upper mounting bracket (4).

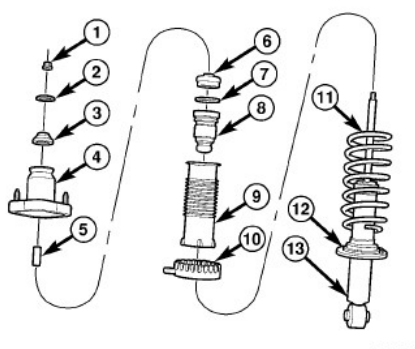


81c588c0

NOTE: If the coil spring needs to be serviced, proceed with the next step, otherwise, proceed with Step #11.

10. Release the tension from the coil spring by backing off the compressor drive completely. Push back the compressor hooks and remove the coil spring.

11. Inspect the shock assembly components for the following and replace as necessary:



81c588c0

- Inspect the shock absorber (damper) (13) for shaft binding over the full stroke of the shaft.
- Inspect the jounce bumper (8) for cracks and signs of deterioration.
- Inspect the dust shield (9) for cracks and tears.
- Check the upper mounting bracket (4) for cracks and distortion and its retaining studs for any sign of damage.
- Inspect the upper (3) and lower (6) bushings for material deterioration and signs of deterioration. Inspect the sleeve (5) for wear and distortion.
- Inspect the upper (10) and lower (12) spring isolators for material deterioration and distortion.
- Inspect the coil spring (11) for any sign of damage to the coating.

NOTE: For reassembly, (Refer to 17 - Rear Suspension/SHOCK ABSORBER, Suspension - Assembly)

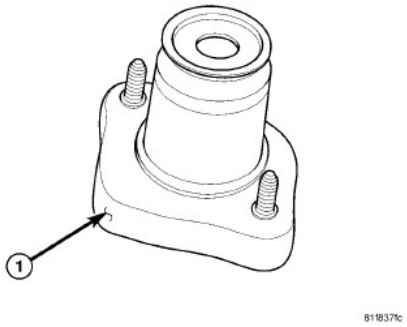
WITH THIRD ROW SEATING

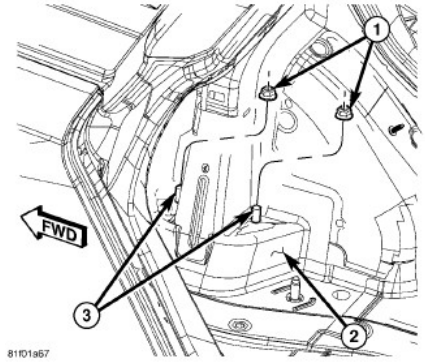
Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE:

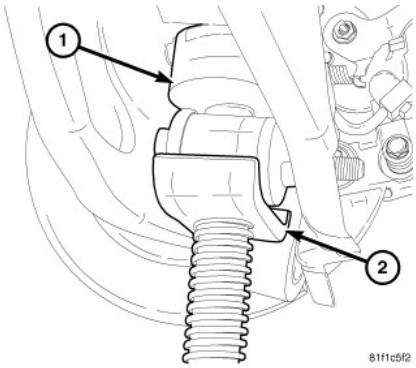
When installing the shock assembly into the body bracket in the following step, be sure to position the upper mounting bracket so that the angular formed side (as viewed from above) of the mounting bracket flange (1) is facing outboard of vehicle (opposite side of bracket is rounded).



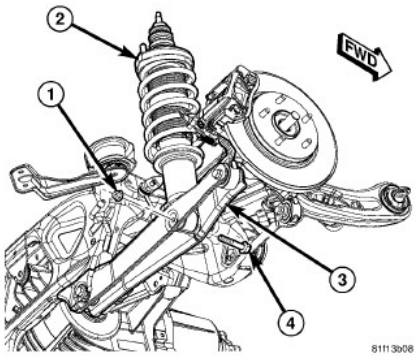
1. Insert the lower end of the shock assembly down though the lower control arm from above just enough to clear the body with the upper mount, then lift it up, inserting the upper mounting studs (3) through the body bracket (2).



2. If equipped with load-leveling shocks, place a jack (2) against the lower shock eye and support the lower end of the shock assembly (1). Lift the shock assembly using the jack until the hole in the lower shock eye lines up with that in the lower control arm.

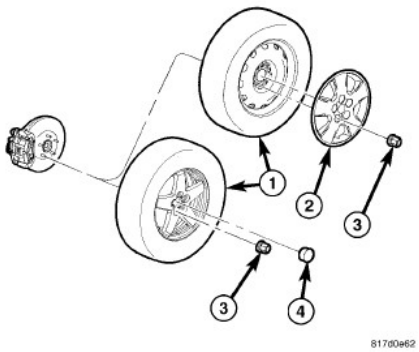


3. Install the mounting bolt (4) and nut (1) fastening the shock assembly (2) to the lower control arm (3). Do not tighten at this time.

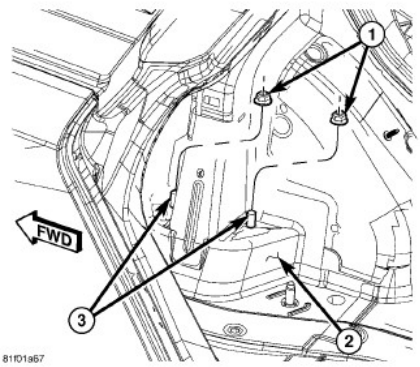


4. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

5. Lower the vehicle.



6. Install the two nuts (1) on the studs (3) securing the shock assembly to the body bracket (2). Tighten the mounting nuts to 45 N·m (33 ft. lbs.).



7. Install the rear quarter trim panel and components removed to access it. (Refer to 23 - Body/Interior/PANEL, Quarter Trim - Installation)

8. Position the vehicle on an alignment rack/drive-on lift. Raise the lift as necessary to access the shock mounting bolt and nut.

9. Tighten the shock assembly lower mounting bolt nut (1) to 99 N·m (73 ft. lbs.).

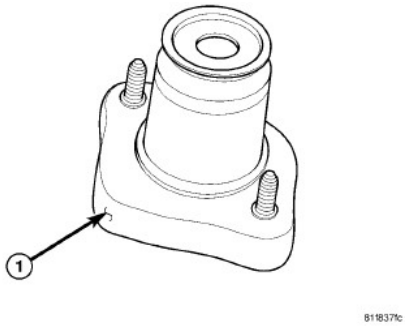
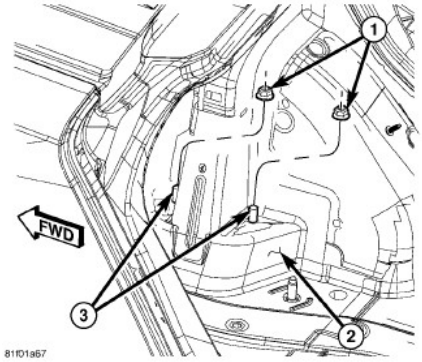
Labor Operations: Click to display a list of Labor Operations associated with this procedure

NOTE:

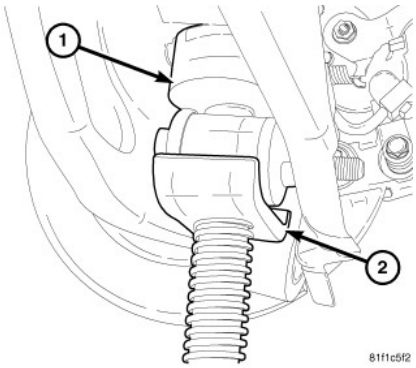
When installing the shock assembly into the body bracket in the following step, be sure to position the upper mounting bracket so that the angular formed side (as viewed from above) of the mounting bracket flange (1) is facing outboard of vehicle (opposite side of bracket is rounded).



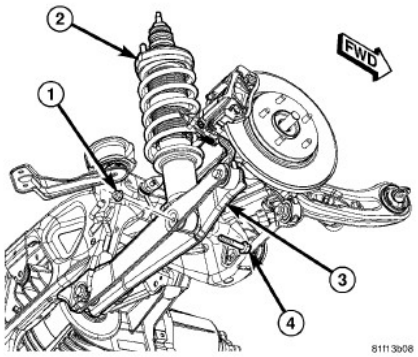
1. Insert the lower end of the shock assembly down though the lower control arm from above just enough to clear the body with the upper mount, then lift it up, inserting the upper mounting studs (3) through the body bracket (2).



2. If equipped with load-leveling shocks, place a jack (2) against the lower shock eye and support the lower end of the shock assembly (1). Lift the shock assembly using the jack until the hole in the lower shock eye lines up with that in the lower control arm.

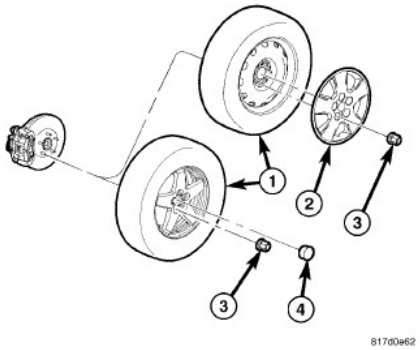


3. Install the mounting bolt (4) and nut (1) fastening the shock assembly (2) to the lower control arm (3). Do not tighten at this time.

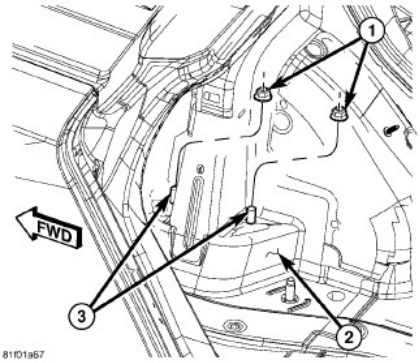


4. Install the tire and wheel assembly (1) (Refer to 22 - Tires and Wheels - Installation) . Install and tighten wheel mounting nuts (3) to 135 N·m (100 ft. lbs.).

5. Lower the vehicle.



6. Install the two nuts (1) on the studs (3) securing the shock assembly to the body bracket (2). Tighten the mounting nuts to 45 N·m (33 ft. lbs.).



7. Remove four nuts, remove load floor.

8. Fold the access panel back into place.

9. Install the load floor.

10. Position the vehicle on an alignment rack/drive-on lift. Raise the lift as necessary to access the shock mounting bolt and nut.

11. Tighten the shock assembly lower mounting bolt nut (1) to 99 N·m (73 ft. lbs.).

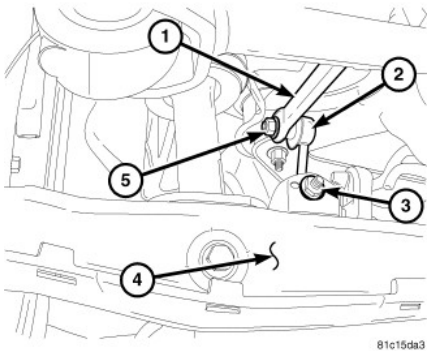
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

CAUTION: **Before installing the nuts in the following steps, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**



1. Install the stabilizer link (2) upper stud in the end of the stabilizer bar (1) from the inboard side. Install the nut (5) on the upper stud and while holding the stabilizer link stud stationary, tighten the nut to 100 N·m (74 ft. lbs.).

NOTE: When attaching a stabilizer bar link to the lower control arm it is important that the lower mounting stud be positioned properly. The lower mounting stud on the right side link needs to point toward the front of the vehicle when inserted through the lower control arm mounting flange. The left side link lower stud needs to point toward the rear of the vehicle. Otherwise the suspension geometry will not function properly.

2. Attach the stabilizer bar link (2) to the lower control arm (4). Install the nut (3) and while holding the stabilizer bar link lower stud stationary, tighten the nut (3) to 100 N·m (74 ft. lbs.).

3. Lower the vehicle.

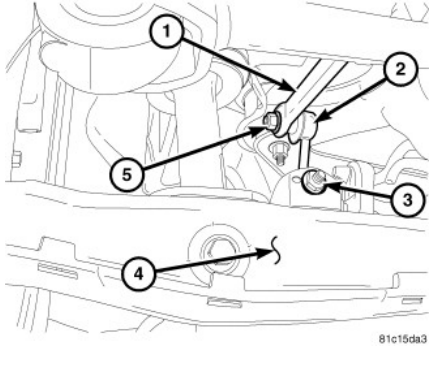
REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure

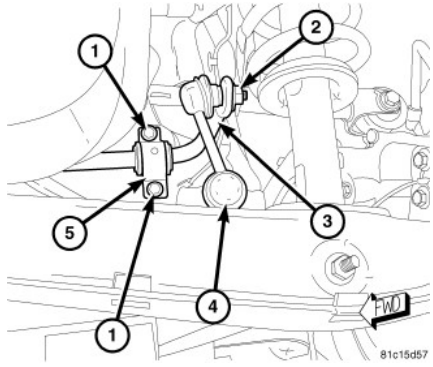
1. Raise and support the vehicle. (Refer to 04 - Vehicle Quick Reference/Hoisting - Standard Procedure)
2. While holding the stabilizer bar link lower stud stationary, remove the nut (3) securing the link (2) to the lower control arm (4).
3. While holding the stabilizer bar link upper stud stationary, remove the nut (5) securing the link (2) to the stabilizer bar (1).
4. Remove the stabilizer bar link (2).



INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. If required, install the two cushions (bushings) on the stabilizer bar (one on each side) utilizing the slit cut into the cushions.



NOTE: When installing the stabilizer bar on a vehicle with all-wheel-drive, position the bar so that the bar loops over the axle half shafts once installed, not under the axle half shafts.

2. Position the stabilizer bar (3) on the rear crossmember.

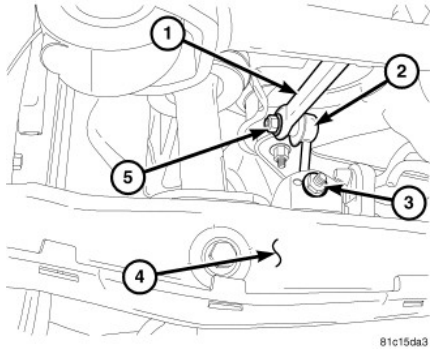
CAUTION: **Before installing the screws in the following step, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**

3. Install the two retainers (5 - right side shown) over the cushions at the mounting holes and install the retainer screws (1). Do not tighten the screws at this time.

4. If equipped with all-wheel-drive, install the rear driveline module (Refer to 03 - Differential and Driveline/Rear Driveline Module - Installation) .

CAUTION: **Before installing the nut in the following step, it is especially important to clean the threads and apply Mopar® Lock AND Seal Adhesive or equivalent.**

5. On each side of the vehicle, install the stabilizer link (2) upper stud in the end of the stabilizer bar (1). Install the nut (5) on the upper stud and while holding the stabilizer link stud stationary, tighten the nut to 100 N·m (74 ft. lbs.).



6. On each side of the vehicle, tighten the stabilizer bar retainer screws (1) to 25 N·m (18 ft. lbs.).

7. Lower the vehicle.

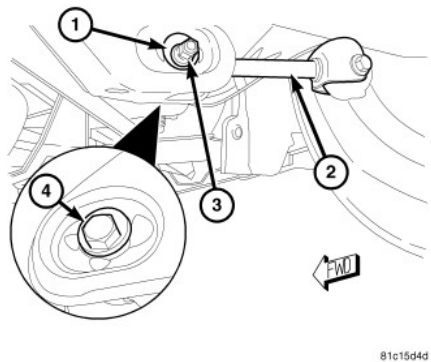
INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

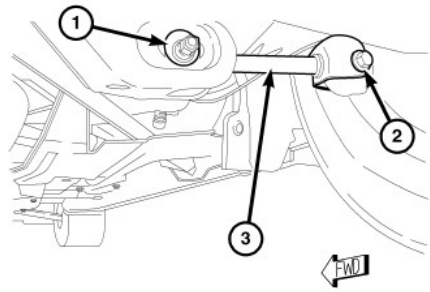
CAUTION: **When installing the cam bolt (4) and washer make sure the cams stay inside the abutments built into the crossmember. Failure to do so can damage the abutments and make toe adjustment difficult.**



1. Position the toe link (2) and install the cam bolt (4) from the front through the crossmember and link. Match the cam on the bolt to the marks made during removal or position the top of the cam to the 12 O'clock position.

2. Install the cam washer (1) and nut (3) securing the toe link (2) to the crossmember. Do not tighten at this time.

3. Install the mounting bolt (2) and nut securing the link to the knuckle. To install the bolt it may be necessary to flex the trailing link at the body mount bushing inward or outward using an appropriate prying tool. Do not tighten at this time.



81c15d38

4. Lower the vehicle.

5. Position the vehicle on an alignment rack/drive-on lift. Raise the vehicle as necessary to access mounting bolts and nuts.

6. Tighten the toe link mounting bolt nut at the knuckle to 105 N·m (77 ft. lbs.).

7. Perform wheel alignment as necessary. (Refer to 02 - Front Suspension/Wheel Alignment - Standard Procedure)

8. Once rear toe is set, while holding the cam bolt (4) head stationary, tighten the toe link mounting cam bolt nut (3) to 95 N·m (70 ft. lbs.).

WARNING

WARNING:

Chrysler LLC does not manufacture any vehicles or replacement parts that contain asbestos. Aftermarket products may or may not contain asbestos. Refer to aftermarket product packaging for product information.

Whether the product contains asbestos or not, dust and dirt can accumulate on brake parts during normal use. Follow practices prescribed by appropriate regulations for the handling, processing and disposing of dust and debris.

CAUTION:

Only frame contact or wheel lift hoisting equipment can be used on this vehicle. It cannot be hoisted using equipment designed to lift a vehicle by the rear axle. If this type of hoisting equipment is used, damage to rear suspension components will occur.

CAUTION:

All-Wheel-Drive only - Wheel bearing damage will result if after loosening the hub nut, the vehicle is rolled on the ground or the weight of the vehicle is allowed to be supported by the tires for a length of time.

NOTE:

If a rear suspension component becomes bent, damaged or fails, no attempt should be made to straighten or repair it. Always replace it with a new component.

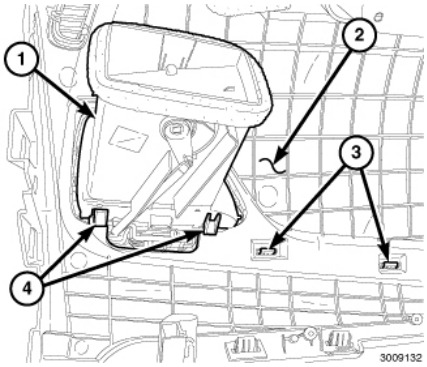
OUTBOARD OUTLETS

NOTE: Underside of instrument panel cover shown. Instrument panel duct removed from view for clarity.

NOTE: Make sure that the air outlet is properly aligned to the instrument panel opening and that the foam seal on the outlet is properly installed.



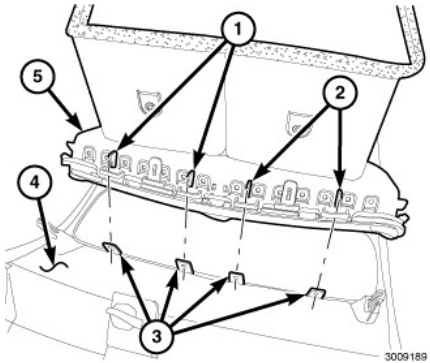
1. Install the outboard instrument panel air outlet (1) through the opening in the instrument panel cover (2) and connect it to the duct
2. Engage the two retaining tabs located on the top of each outlet to the instrument panel cover.
3. Engage the two retaining tabs (4) located on the bottom of each outlet to the instrument panel cover. Make sure all four retaining tabs are fully engaged.
4. Engage the retaining tabs (3) that secure the outboard air outlet trim panel to the face of the instrument panel cover. Make sure all the retaining tabs are fully engaged.
5. When servicing the passenger side air outlet, install the glove box (Refer to 23 - Body/Instrument Panel/GLOVE BOX, Instrument Panel - Installation)
6. When servicing the driver side air outlet, install the knee blocker (Refer to 23 - Body/Instrument Panel/PANEL, Instrument - Installation)
7. Reconnect the negative battery cable.

CENTER OUTLETS

NOTE: Take the proper precautions to protect the front face of the center bezel from cosmetic damage while performing this procedure.

1. Position the center instrument panel air outlet assembly (5) to the four center bezel tabs (3).

2. Engage the four retaining tabs (1 and 2) that secure the center instrument panel air outlet assembly to the center bezel (4). Make sure all the retaining tabs are fully engaged.



3. Install the three screws (2) that secure the center instrument panel air outlet assembly (1) to the center bezel (3). Tighten the screws to 1.2 N·m (10 in. lbs.).

NOTE:

Make sure that the air outlets are properly aligned to the instrument panel center duct.

4. Install the center bezel (Refer to 23 - Body/Instrument Panel/BEZEL, Instrument Panel - Installation) .

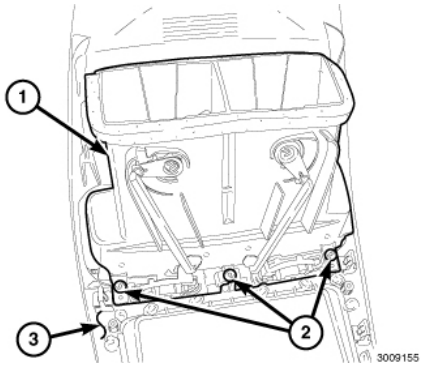
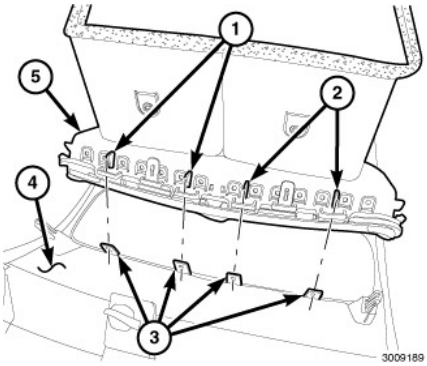
CENTER OUTLETS

NOTE: Take the proper precautions to protect the front face of the center bezel from cosmetic damage while performing this procedure.

1. Remove the center bezel (3) from the instrument panel and place it on a workbench (Refer to 23 - Body/Instrument Panel/BEZEL, Instrument Panel - Removal) .
2. Remove the three screws (2) that secure the center instrument panel air outlet assembly (1) to the center bezel (3).



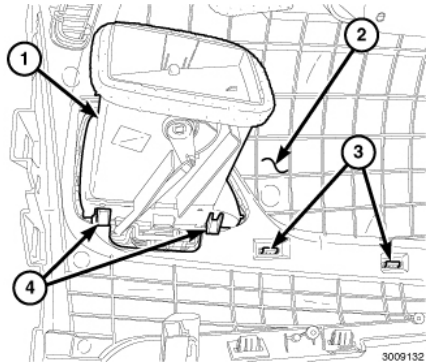
3. Using Trim Stick C-4755 or equivalent, carefully disengage the four retaining tabs (1 and 2) that secure the center instrument panel air outlet assembly (5) to the center bezel (4).
4. Separate the center instrument panel air outlet assembly from the four center bezel tabs (3) by carefully pulling the outlet assembly straight off the bezel.



OUTBOARD OUTLETS

NOTE: The outboard air outlets can be serviced without removing the instrument panel cover.

NOTE: Underside of instrument panel cover shown. Instrument panel duct removed from view for clarity.



1. Disconnect and isolate the negative battery cable.
2. When servicing the passenger side air outlet, remove the glove box (Refer to 23 - Body/Instrument Panel/GLOVE BOX, Instrument Panel - Removal)
3. When servicing the driver side air outlet, remove the knee blocker (Refer to 23 - Body/Instrument Panel/PANEL, Instrument - Removal)

NOTE: The air outlet trim panels are serviced with the air outlets as an assembly.

4. Using Trim Stick C-4755 or equivalent, disengage the retaining tabs (3) that secure the outboard air outlet trim panel to the face of the instrument panel cover (2).
5. Reach up behind the instrument panel and disengage the two lower retaining tabs (4) that secure each outboard air outlet (1) to the back of the instrument panel cover.

NOTE: If the foam seal on an air outlet is deformed or damaged, the seal must be replaced.

6. Carefully twist and rock the outboard air outlet to disengage the two retaining tabs located on the top of each outlet from the instrument panel cover.
7. Push the outboard air outlet(s) straight out of the instrument panel cover.

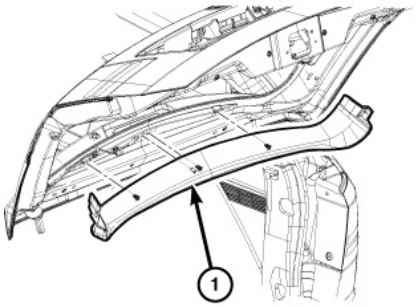
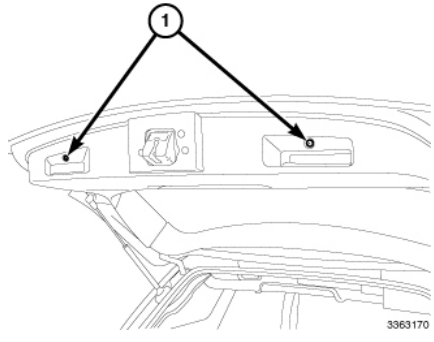
4. Using trim stick C-4755 or equivalent, pry around the perimeter of the upper trim panel (1) to disengage the retaining clips and remove the trim panel.



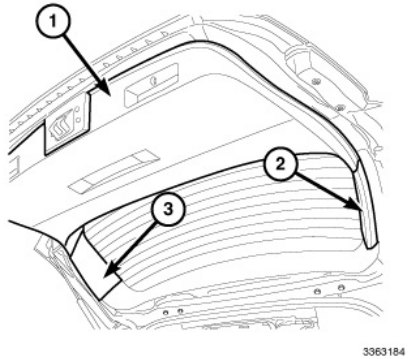
3363155

TRIM PANEL - LOWER

NOTE: The side trim panels can be removed in conjunction with the lower liftgate trim panel.

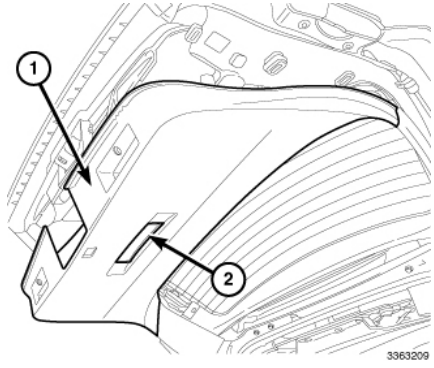


1. Open the liftgate.
2. Remove the two lower screws (1).



3. If removing the side trim panels (2, 3) in conjunction with the lower trim panel, disengage the retaining clips using trim stick C-4755 or equivalent.
4. Using trim stick C-4755 or equivalent, pry around the perimeter of the lower trim panel (1) to disengage the retaining clips.

NOTE: View shown with side panels shown.



5. Position the lower trim panel (1) slightly away from the door and disconnect the wiring harness from the liftgate lamp (2).
6. Remove the lower trim panel (1).

2014 Dodge JC - DODGE JOURNEY

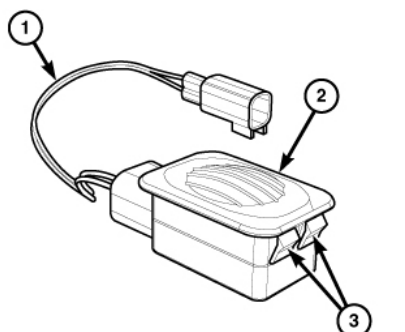
Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

DESCRIPTION

Vehicles equipped with the Passive Entry (PE) system have a unique liftgate handle and light bar unit that incorporates a PE liftgate lock and unlock switch and push button (2). This tactile switch is secured to the underside of the left side of the handle and light bar unit by two latch features (3) integral to the switch housing. The switch button extends through a clearance hole in the handle housing so that it can be accessed on the outer surface of the handle to the left side of center.

A short two-wire pigtail and connector (1) connects the switch to the vehicle electrical system through a dedicated take out and connector of the liftgate wire harness.

The PE liftgate lock and unlock switch cannot be adjusted or repaired. If the switch is damaged or ineffective, the entire switch unit must be replaced.



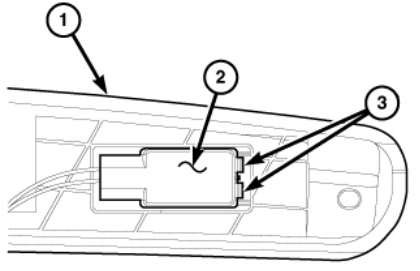
2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. With the liftgate lock and unlock switch latch tabs (3) oriented toward the outboard side of the mounting hole, insert switch pigtail wire and connector through the mounting hole from the outside of the handle and light bar unit (1).
2. Engage the fixed locator tabs on the pigtail wire end of the switch (2) above the inboard side of the mounting hole in the handle and light bar unit.
3. While holding the pigtail wire end of the switch firmly against the inboard side of the mounting hole, push the latch tab end of the switch through the mounting hole far enough for the two latch tabs to snap into place above the outboard side of the mounting hole in the handle and light bar unit.



3126517

4. Reinstall the handle and light bar unit onto the liftgate outer panel. (Refer to 23 - Body/Decklid/Hatch/Liftgate/Tailgate/HANDLE, Exterior - Installation) .
5. Reconnect the battery negative cable.

2014 Dodge JC - DODGE JOURNEY

Submodel: | **Engine Type:** V6 | **Liters:** 3.6L
Fuel Delivery: | **Fuel:**

OPERATION

The Passive Entry (PE) liftgate lock and unlock switch is a normally open switch that is hard wired to the Radio Frequency Hub (RF Hub) through a signal circuit and a return circuit. The RF Hub continually monitors the condition of the PE liftgate lock and unlock switch and circuits, and will store a Diagnostic Trouble Code (DTC) for any fault that is detected in these circuits.

When the switch button is depressed, it provides a signal to the RF Hub. The RF Hub determines the system response based upon the inputs it receives through the authentication process with each detected FOB with Integrated Key (FOBIK). If the authentication process is successful, the RF Hub sends an electronic **lock request** or **unlock request** message to the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the Controller Area Network (CAN) data bus, and the BCM energizes the liftgate latch lock motor accordingly.

The hard wired circuits between the PE liftgate lock and unlock switch and the RF Hub may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the switch or the electronic controls and communication between other modules and devices that provide some features of the PE system. The most reliable, efficient, and accurate means to diagnose the PE system or the electronic controls and communication related to liftgate lock and unlock switch operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

ADJUSTMENTS

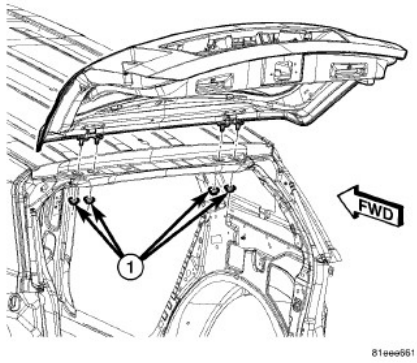
Special Tools: Click to display a list of tools used in this procedure

NOTE:

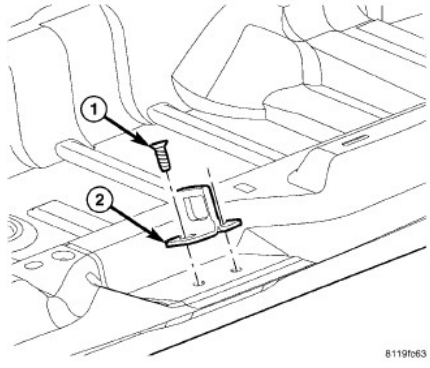
The position of the liftgate can be adjusted upward or downward by the use of slots in the hinge. An inward or outward adjustment is achieved by use of slots in the body. If an inward or outward adjustment is needed, use a body sealer on the hinge to body mating surface.

In/out

1. Using a trim stick C-4755 or equivalent, remove the upper rear headliner trim.
2. For the upper lift gate adjustments, loosen the six hinge to header bolts (1) and adjust to specifications (Refer to 23 - Body/Body Structure/Gap and Flush - Specifications)
3. Tighten the hinge bolts to 28 N·m (21 ft. lbs.).

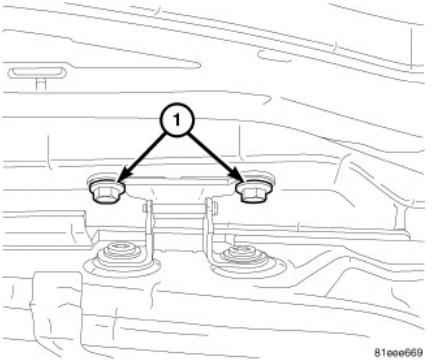


4. For the lower lift gate adjustments, loosen the striker screws (1) and adjust to specifications (Refer to 23 - Body/Body Structure/Gap and Flush - Specifications)
5. Tighten the striker screws to 28 N·m (21 ft. lbs.).
6. Position the upper rear headliner trim and seat fully.



Up/Down and Left/Right

1. Loosen the hinge to liftgate bolts (2).



2. Loosen the striker screws (1).

3. Adjust the liftgate up/down position and tighten the hinge bolts to 28 N·m (21 ft. lbs.). (Refer to 23 - Body/Body Structure/Gap and Flush - Specifications)

4. Confirm the lower liftgate in/out position and tighten the striker screws to 28 N·m (21 ft. lbs.).

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure
Special Tools: Click to display a list of tools used in this procedure

WARNING: **Do not disconnect the support rod cylinders with the liftgate closed. The support rod pistons are operated by high pressure gas. This pressure could cause damage and/or personal injury if they are removed while the pistons are compressed.**

1. Open and support the liftgate.
2. Using a trim stick C-4755 or equivalent, remove the upper rear headliner trim.
3. Remove the support cylinders from the liftgate. (Refer to 23 - Body/Decklid/Hatch/Liftgate /Tailgate/PROP, Gas - Removal) .
4. Disconnect the wire harnesses and the washer hose.
5. Using a grease pencil or equivalent, mark the hinge location.
6. Remove the liftgate to body fasteners (1) and remove liftgate from vehicle.

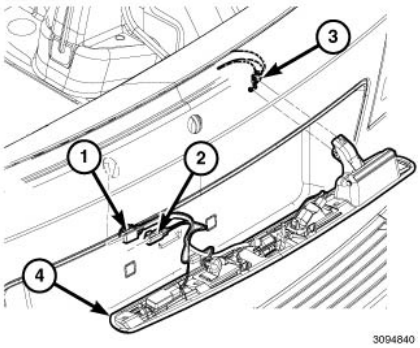
INSTALLATION

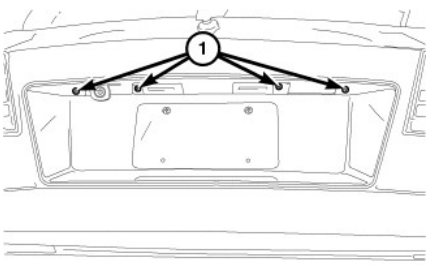
Labor Operations: Click to display a list of Labor Operations associated with this procedure

1. Position the liftgate handle assembly (4) to the liftgate and connect the liftgate handle latch cable (3).
2. Connect the electrical connectors as equipped (1 and 2).



3094840

3. Install the liftgate handle assembly onto the liftgate and install the four screws (1). Tighten the screws securely.



81eee5de

4. Install the nut (1) that secures the liftgate handle assembly to the inside of the liftgate (2). Tighten the nut securely.
5. Install the liftgate trim panel (Refer to 23 - Body/Decklid/Hatch/Liftgate/Tailgate/PANEL, Trim - Installation) .
6. Reconnect the negative battery cable.

REMOVAL

Labor Operations: Click to display a list of Labor Operations associated with this procedure
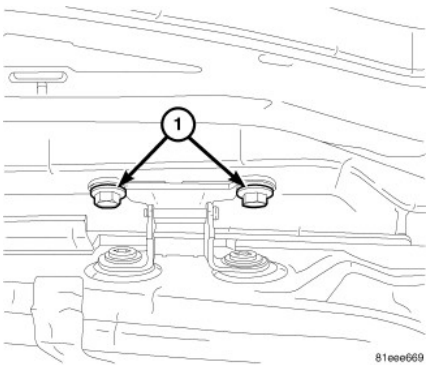
Special Tools: Click to display a list of tools used in this procedure

NOTE: It is not necessary to remove the liftgate to replace one or both hinges. The hinges can be replaced one at a time.

NOTE: A suitable body sealant should be used when removing or moving the hinges.

1. Place the liftgate in the full up position.
2. Support liftgate on a suitable lifting device.
3. Using a trim stick C-4755 or equivalent, remove the upper rear headliner trim.
4. Mark outline of hinge on the inside of liftgate to aid in installation.
5. Remove the upper hinge bolts (1).



6. Remove the lower hinge bolts (1).
7. Remove hinge from vehicle.

INSTALLATION

Labor Operations: Click to display a list of Labor Operations associated with this procedure

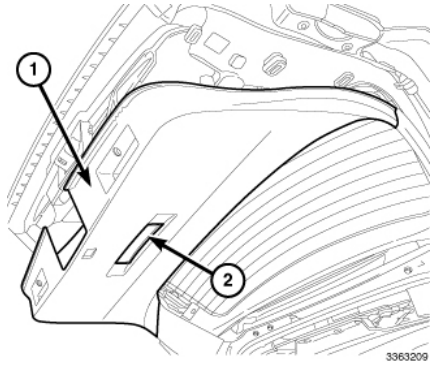
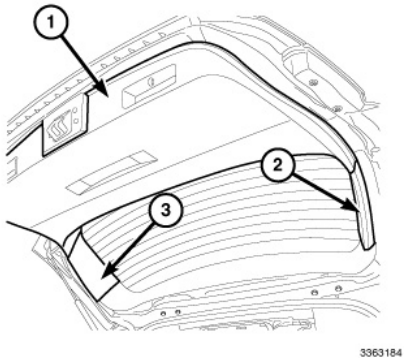
TRIM PANEL - LOWER

NOTE: The side trim panels can be installed in conjunction with the lower liftgate trim panel.

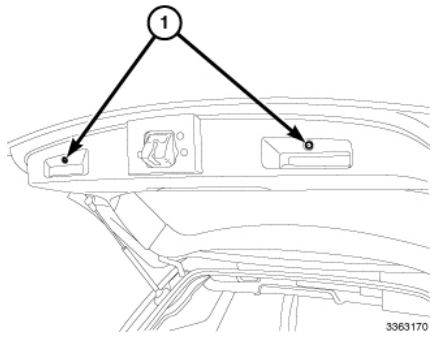
NOTE: View shown with side panels shown.



1. Position the lower trim panel (1) towards the door and connect the wiring harness to the liftgate lamp (2).



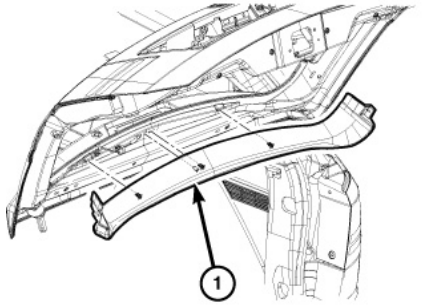
2. Align the trim panel's retaining clips to the openings in the liftgate, hand tap around the perimeter of the lower trim panel (1) to engage the retaining clips.
3. If installing the side trim panels (2, 3) in conjunction with the lower trim panel (1), hand tap to engage the retaining clips.



4. Install the two lower screws (1). Tighten the screws securely.
5. Close the liftgate.

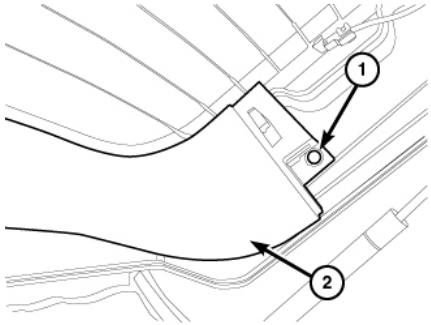
TRIM PANEL - UPPER

1. Align the trim panel's retaining clips to the openings in the liftgate, hand tap around the perimeter of the upper trim panel (1) to engage the retaining clips.



3363155

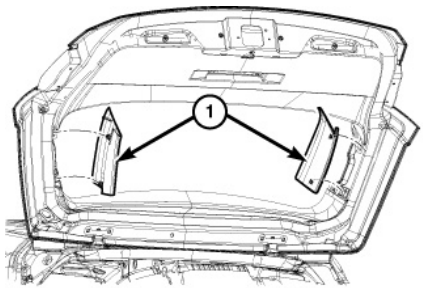
2. Install the pushpin fasteners (1) to the upper trim panel (2). Repeat for the opposite side.
3. Install the left and right side trim panels.
4. Close the liftgate.



3363122

TRIM PANEL - SIDES

1. Align the trim panel's retaining clips to the openings in the liftgate, hand tap around the perimeter of the side trim panel (1) to engage the retaining clips. Repeat on the opposite side.
2. Close the liftgate.



3363134

BATTERY

The battery Group Size number, the Cold Cranking Amperage (CCA) rating, and the Reserve Capacity (RC) rating or Ampere-Hours (AH) rating can be found on the original equipment battery label. Be certain that a replacement battery has the correct Group Size number, as well as CCA, and RC or AH ratings that equal or exceed the original equipment specification for the vehicle being serviced. Battery sizes and ratings are discussed in more detail below.

NOTE: Vehicles equipped with a diesel engine utilize a unique battery. The specifications for this battery may differ from the standards shown here. Refer to the battery manufacturer for detailed specifications.
